# Python 2.7 Quick Reference

## **Contents**

- Front matter
- Invocation Options
- Environment variables
- Lexical entities: keywords, identifiers, string literals, boolean constants, numbers, sequences, dictionaries, sets, operators
- Basic types and their operations: None, bool, Numeric types, sequence types, list, dictionary, string, file, set, named tuples, date/time
- Advanced types
- · Statements: assignment, conditional expressions, control flow, exceptions, name space, function def, class def
- Iterators; Generators; Descriptors; Decorators
- Built-in Functions
- Built-in Exceptions
- Standard methods & operators redefinition in user-created Classes
- Special **informative state attributes** for some types
- Important modules: sys, os, posix, posixpath, shutil, time, string, re, math, compressions
- List of modules in the base distribution
- Workspace exploration and idiom hints
- Python mode for Emacs

## Front matter

Version 2.7 (What's new?)

Check updates at http://rgruet.free.fr/#QuickRef.

Please report errors, inaccuracies and suggestions to Richard Gruet (pqr at rgruet.net).

- Python 2.4 Reference Card (cheatsheet) by Laurent Pointal, designed for printing (15 pages).
- Online Python 2.2 Quick Reference by the New Mexico Tech Computer Center.

Tip: From within the Python interpreter, type help, help(object) or help("name") to get help.

## **Invocation Options**

python[w] [-BdEhimOQsStuUvVWxX3] [-c command | scriptFile | -] [args]
 (pythonw does not open a terminal/console; python does)

#### **Invocation Options**

Invocation Options		
Option	Effect	
-B	Prevents module imports from creating .pyc or .pyo files (see also envt variable PYTHONDONTWRITEBYTECODE=x and	
	attribute sys.dont_write_bytecode).	
-d	Output parser debugging information (also PYTHONDEBUG=x)	
-E	Ignore environment variables (such as PYTHONPATH)	
-h	Print a help message and exit (formerly -?)	
-i	Inspect interactively after running script (also PYTHONINSPECT=x) and force prompts, even if stdin appears not to be	
	a terminal.	
-m	Search for module on sys.path and runs the module as a script. (Implementation improved in 2.5: module runpy)	
module		
-O	Optimize generated by tecode (also PYTHONOPTIMIZE=x). Asserts are suppressed.	
-00	Remove doc-strings in addition to the -O optimizations.	
-Q arg	Division options: -Qold (default), -Qwarn, -Qwarnall, -Qnew	
-s	Disables the user-specific module path (also PYTHONNOUSERSITE=x)	
-S	Don't perform import site on initialization.	
-t	Issue warnings about inconsistent tab usage (-tt: issue errors).	
-u	Unbuffered binary stdout and stderr (also PYTHONUNBUFFERED=x).	
-U	Force Python to interpret all string literals as Unicode literals.	
-v	Verbose (trace import statements) (also PYTHONVERBOSE=x).	
-V	Print the Python version number and exit.	
-W arg	Warning control (arg is action:message:category:module:lineno)	
-X	Skip first line of source, allowing use of non-unix Forms of #!cmd	
<del>-X</del>	Disable class based built-in exceptions (for backward compatibility management of exceptions)	
-3	Emit a DeprecationWarning for Python 3.x incompatibilities that 2to3 cannot trivially fix	
-c	Specify the command to execute (see next section). This terminates the option list (following options are passed as	
command	arguments to the command).	
scriptFile	The name of a python file (.py) to execute. Read from stdin.	
-	Program read from stdin (default; interactive mode if a tty).	
args	Passed to script or command (in sys.argv[1:])	
	If no scriptFile or command, Python enters interactive mode.	

- Available **IDEs** in std distrib: **IDLE** (tkinter based, portable), **Pythonwin** (on Windows). Other free IDEs: IPython (enhanced interactive Python shell 2011), Eric (2011), SPE (2010), BOA constructor (GUI Builder 2011), PyDev (Eclipse plugin 2011).
- Typical python module header:

```
#!/usr/bin/env python
# -*- coding: latin1 -*-
```

Since 2.3 the *encoding* of a Python source file must be declared as one of the two first lines (or defaults to 7 **bits Ascii**) [PEP-0263], with the format:

```
# -*- coding: encoding -*-
```

Std *encodings* are defined here, e.g. ISO-8859-1 (aka latin1), iso-8859-15 (latin9), UTF-8... Not all encodings supported, in particular UTF-16 is not supported.

- It's now a **syntax error** if a module contains string literals with 8-bit characters but doesn't have an encoding declaration (was a warning before).
- Since 2.5, from \_\_future\_\_ import feature statements must be declared at **beginning** of source file.
- Site customization: File sitecustomize.py is automatically loaded by Python if it exists in the Python path (ideally located in \${PYTHONHOME}/lib/site-packages/).
- Tip: when launching a Python script on Windows,

```
<pythonHome>\python myScript.py args ... can be reduced to:
myScript.py args ... if <pythonHome> is in the PATH envt variable, and further reduced to:
myScript args ... provided that .py; .pyw; .pyc; .pyo is added to the PATHEXT envt variable.
```

## **Environment variables**

#### **Environment variables**

Variable Effect

PYTHONHOME **PYTHONPATH** 

**PYTHONSTARTUP** 

Alternate *prefix* directory (or *prefix:exec\_prefix*). The default module search path uses *prefix*/lib Augments the default search path for module files. The format is the same as the shell's <code>\$PATH</code>: one or more directory pathnames separated by ':' or ';' without spaces around (semi-) colons! On Windows Python first searches for Registry key

HKEY\_LOCAL\_MACHINE\Software\Python\PythonCore\x.y\PythonPath (default value). You can create a key named after your application with a default string value giving the root directory path of your appl.

Alternatively, you can create a text file with a .pth extension, containing the path(s), one per line, and put the file somewhere in the Python search path (ideally in the site-packages/directory). It's better to create a .pth for each application, to make easy to uninstall them. If this is the name of a readable file, the Python commands in that file are executed before the

first prompt is displayed in interactive mode (no default).

PYTHONDEBUG If non-empty, same as -d option
PYTHONINSPECT If non-empty, same as -i option
PYTHONOPTIMIZE If non-empty, same as -O option
PYTHONUNBUFFERED If non-empty, same as -u option
PYTHONVERBOSE If non-empty, same as -v option

PYTHONCASEOK If non-empty, ignore case in file/module names (imports)

 $\label{eq:pythonout} {\tt PYTHONDONTWRITEBYTECODE} \quad \text{If non-empty, same as -B option}$ 

PYTHONIOENCODING Alternate encodingname or encodingname: errorhandler for stdin, stdout, and stderr, with

the same choices accepted by str.encode().

PYTHONUSERBASE Provides a private site-packages directory for **user-specific** modules. [PEP-0370]

- On Unix and Mac OS X, defaults to ~/.local/, and modules are found in a version-specific

subdirectory like lib/python2.6/site-packages.

- On Windows, defaults to  $APPDATA\$ /Python and Python26/site-packages.

PYTHONNOUSERSITE If non-empty, same as -s option

PYTHONWARNINGS Allows controlling warnings, same as -W option

## Notable lexical entities

#### **Keywords**

and del for is raise assert elif from lambda return break else global not try

```
class except if or while continue exec import pass with def finally in print yield
```

- (List of keywords available in std module: **keyword**)
- Illegitimate Tokens (only valid in strings): \$ ? (plus @ before 2.4)
- A statement must all be on a single line. To break a statement over multiple lines, use "\", as with the C preprocessor. Exception: can always break when inside any (), [], or {} pair, or in triple-quoted strings.
- More than one statement can appear on a line if they are separated with semicolons (";").
- Comments start with "#" and continue to end of line.

## **Identifiers**

(letter | "\_") (letter | digit | "\_")\*

- Python identifiers keywords, attributes, etc. are **case-sensitive**.
- Special forms: \_ident (not imported by 'from module import \*'); \_\_ident\_\_ (system defined name); \_\_ident (class-private name mangling).

## String literals

Two flavors: str (standard 8 bits locale-dependent strings, like ascii, iso 8859-1, utf-8, ...) and unicode (16 or 32 bits/char in utf-16 mode or 32 bits/char in utf-32 mode); one common ancestor basestring.

```
"a string enclosed by double quotes"
'another string delimited by single quotes and with a "inside'
""a string containing embedded newlines and quote (') marks, can be delimited with triple quotes.""
""" may also use 3-double quotes as delimiters """

b"An 8-bit string" - A bytes instance, a forward-compatible form for an 8-bit string'
B"Another 8-bit string"
u'a unicode string'
U"Another unicode string"
r'a raw string where \ are kept (literalized): handy for regular expressions and windows paths!'
R"another raw string" -- raw strings cannot end with a \
ur'a unicode raw string'
UR"another raw unicode"
```

- Use \ at end of line to continue a string on next line.
- Adjacent strings are concatened, e.g. 'Monty ' 'Python' is the same as 'Monty Python'.
- u'hello' + ' world' --> u'hello world' (coerced to unicode)

#### String Literal Escapes

Escape	Meaning
\newline	Ignored (escape newline)
\\	Backslash (\)
\ <b>e</b>	Escape (ESC)
$\setminus \mathbf{v}$	Vertical Tab (VT)
\'	Single quote (')
\ <b>f</b>	Formfeed (FF)
\000	char with octal value ooo
\"	Double quote (")
\n	Linefeed (LF)
∖a	Bell (BEL)
\ <b>r</b>	Carriage Return (CR)
$\backslash \mathbf{x}hh$	char with hex value <i>hh</i>
\ <b>b</b>	Backspace (BS)
\t	Horizontal Tab (TAB)
\uxxxx	Character with 16-bit hex value xxxx (unicode only)
\Uxxxxxxxxx	Character with 32-bit hex value xxxxxxx (unicode only)
$\N{name}$	Character named in the Unicode database (unicode only), e.g. u'\N{Greek Small Letter Pi}' <=>
	u'\u03c0'.
	(Conversely, in module unicodedata, unicodedata.name(u'\u03c0') == 'GREEK SMALL LETTER PI')
\AnyOtherChar	left as-is, including the backslash, e.g. str('\z') == '\\z'

- NUL byte (\000) is **not** an end-of-string marker; NULs may be embedded in strings.
- Strings (and tuples) are immutable: they cannot be modified.

## **Boolean constants**

- True
- False

Since 2.3, they are of new type bool.

#### **Numbers**

```
    Decimal integer: 1234, 1234567890546378940L (or 1)
    Binary integer: 0b10, 0B10, 0b1010101010101010101010101010101010 (begins with a 0b or 0B)
```

• Octal integer: 0177, 00177, 00177, 01777777777777 (begins with a 0, 00, or 00)

• Long integer (unlimited precision): 1234567890123456L (ends with L or 1) or long (1234)

• Float (double precision): 3.14e-10, .001, 10., 1E3

• Complex: 1J, 2+3J, 4+5j (ends with J or j, + separates (float) real and imaginary parts)

Integers and long integers are unified starting from release 2.2 (the L suffix is no longer required)

## **Sequences**

Strings and tuples are immutable, lists are mutable.

- Strings (types str and unicode) of length 0, 1, 2 (see above) ", '1', "12", 'hello\n'
- Tuples (type tuple) of length 0, 1, 2, etc: O(1,)(1,2) # parentheses are optional if len > 0
- Lists (type list) of length 0, 1, 2, etc: [[1][1,2]
- Indexing is o-based. Negative indices (usually) mean count backwards from end of sequence.
- Sequence **slicing** [starting-at-index: but-less-than-index[:step]]. Start defaults to 0, end to len(sequence), step to 1.

```
a = (0,1,2,3,4,5,6,7)
a[3] == 3
a[-1] == 7
a[2:4] == (2, 3)
a[1:] == (1, 2, 3, 4, 5, 6, 7)
a[:3] == (0, 1, 2)
a[:] == (0,1,2,3,4,5,6,7) # makes a copy of the sequence.
a[::2] == (0, 2, 4, 6) # Only even numbers.
a[::-1] = (7, 6, 5, 4, 3, 2, 1, 0) # Reverse order.
```

## **Dictionaries (Mappings)**

Dictionaries (type dict) of length 0, 1, 2, etc: {key: value} {1: 'first'} {1: 'first', 'two': 2, key:value}

Keys must be of a *hashable* type; Values can be any type.

Dictionaries are *unordered*, ie. iterating over a dictionary provides key/value pairs in arbitrary order. OrderedDict in the collections module works as regular dictionaries but iterates over keys and values in a guaranteed order depending on when a key was first inserted.

#### Sets\_

A set kan either be mutable or immutable. Curly brackets ({}) are used to surround the contents of the resulting mutable set; set literals are distinguished from dictionaries by not containing colons and values. An empty {} continues to represent an empty dictionary; use set () for an empty set.

### Operators and their evaluation order

#### Operators and their evaluation order

```
Highest Operator
           ,[...] {...} `...`
                                                           Tuple, list & dict. creation; string conv.
                                                           indexing & slicing; attributes, function calls
           s[i] s[i:i] s.attr f(...)
                                                           Unary operators
           +x, -x, \sim x
           x^{**}y
                                                           Power
           x*y x/y x%y
                                                           mult, division, modulo
                                                           addition, substraction
           x+y x-y
                                                           Bit shifting
           x << y \quad x >> y
                                                           Bitwise "and"; also intersection of sets
           x&y
           x^y
                                                           Bitwise exclusive or
                                                           Bitwise "or"; also union of sets
           \mathbf{x} | \mathbf{y}
```

```
x <y x <=y x >y x >=y x ==y x!=y x <>y Comparison,
    x is y x is not y identity,
    x in s x not in s membership
    not x boolean negation
    x and y boolean or
    x or y boolean or

Lowest lambda args: expr anonymous function
```

- Alternate names are defined in module operator (e.g. add and add for +)
- Most operators are overridable

## Basic types and their operations

## Comparisons (defined between any types)

#### **Comparisons**

Comparison	Meaning	Notes
<	strictly less than	(1)
<=	less than or equal to	
>	strictly greater than	
>=	greater than or equal to	
==	equal to	
!= or <>	not equal to	
is	object identity	(2)
is not	negated object identity	(2)

#### Notes:

- Comparison behavior can be overridden for a given class by defining special method cmp .
- (1) X < Y < Z < W has expected meaning, unlike C
- (2) Compare object identities (i.e. id(object)), not object values.

#### None

- None is used as default return value on functions. Built-in single object with type NoneType. Might become a keyword in the
  future.
- Input that evaluates to None does not print when running Python interactively.
- None is now a **constant**; trying to bind a value to the name "None" is now a syntax error.

#### **Boolean operators**

#### Boolean values and operators

Value or Operator	Evaluates to	Notes
built-in <b>bool</b> ( <i>expr</i> )	<b>True</b> if <i>expr</i> is true, <b>False</b> otherwise.	see True, False
None, numeric zeros, empty sequences and mappings	considered False	
all other values	considered True	
not x	<b>True</b> if x is <b>False</b> , else <b>False</b>	
x or $y$	if $x$ is <b>False</b> then $y$ , else $x$	(1)
x and $y$	if $x$ is <b>False</b> then $x$ , else $y$	(1)

#### Notes:

- Truth testing behavior can be overridden for a given class by defining special method nonzero .
- (1) Evaluate second arg only if necessary to determine outcome.

#### Numeric types

Floats, integers, long integers, Decimals.

- Floats (type float) are implemented with C doubles.
- Integers (type int) are implemented with Clongs (signed 32 bits, maximum value is sys.maxint)
- Long integers (type long) have unlimited size (only limit is system resources).
- Integers and long integers are **unified** starting from release 2.2 (the L suffix is no longer required). int() returns a long integer instead of raising OverflowError. Overflowing operations such as 2<<32 no longer trigger FutureWarning and return a long integer.
- Since 2.4, new type Decimal introduced (see module: decimal) to compensate for some limitations of the floating point type, in particular with fractions. Unlike floats, decimal numbers can be represented exactly; exactness is preserved in calculations; precision is user settable via the Context type [PEP 327].

#### Operators on all numeric types

Result	Notes
the absolute value of x	
x converted to integer	(2)
x converted to long integer	(2)
x converted to floating point	
x negated	
x unchanged	
the sum of x and y	
difference of $x$ and $y$	
product of $x$ and $y$	
true division of x by $y: 1/2 \rightarrow 0.5$	(1)
floor division operator: 1//2 -> 0	(1)
$x \bmod ulo y$	
the tuple $(x//y, x\%y)$	
$x$ to the power $y$ (the same as $\mathbf{pow}(x,y)$ )	
	the absolute value of $x$ $x$ converted to integer $x$ converted to long integer $x$ converted to floating point $x$ negated $x$ unchanged the sum of $x$ and $y$ difference of $x$ and $y$ product of $x$ and $y$ true division of $x$ by $y: 1/2 -> 0.5$ floor division operator: $1//2 -> 0$ $x$ modulo $y$ the tuple $(x//y, x\%y)$

#### Notes:

- (1) / is still a floor division (1/2 == 0) unless validated by a from \_\_future\_\_ import division.
- (2) int and long has bit length() method that returns the number of bits necessary to represent its argument in binary.
- classes may override methods \_\_truediv\_\_ and \_\_floordiv\_\_ to redefine these operators.

## Bit operators on integers and long integers

#### Bit operators

OperationResult $\sim x$ the bits of x inverted $x \wedge y$ bitwise exclusive or of x and yx & ybitwise and of x and yx | ybitwise or of x and yx << nx shifted left by n bitsx >> nx shifted right by x bits

#### Complex Numbers

- Type complex, represented as a pair of machine-level double precision floating point numbers.
- The real and imaginary value of a complex number z can be retrieved through the attributes z.real and z.imag.

#### Numeric exceptions

TypeError
raised on application of arithmetic operation to non-number
OverflowError
numeric bounds exceeded
ZeroDivisionError
raised when zero second argument of div or modulo op

## Operations on all sequence types (lists, tuples, strings)

#### Operations on all sequence types

- F	1	
Operation	Result	Notes
x in $s$	True if an item of $s$ is equal to $x$ , else False	(3)
x not in s	False if an item of $s$ is equal to $x$ , else True	(3)
s1 + s2	the concatenation of s1 and s2	
s * n, n*s	n copies of s concatenated	
s[i]	$\ddot{i}$ th item of $s$ , origin o	(1)
s[i:j]	Slice of s from i (included) to j(excluded). Optional step value, possibly negative (default: 1).	(1), (2)
s[i: j:step]		
$s.\mathbf{count}(x)$	returns number of i's for which $s[i] == x$	
s.index(x[, start[,	returns smallest $i$ such that $s[i] = x$ . $start$ and $stop$ limit search to only part of the sequence.	(4)
stop]])		
<b>len</b> ( <i>s</i> )	Length of s	
min(s)	Smallest item of s	
max(s)	Largest item of s	
reversed(s)	[2.4] Returns an iterator on s in reverse order. s must be a sequence, not an iterator (use	
	reversed(list(s)) in this case. [PEP 322]	
<pre>sorted(iterable [, cmp]</pre>	[2.4] works like the new in-place list.sort(), but sorts a <b>new</b> list created from the <i>iterable</i> .	
[, cmp = cmpFunc]		
[, key = keyGetter]		

[, reverse=bool])

مستند

- (1) if i or j is negative, the index is relative to the end of the string, ie len(s)+i or len(s)+j is substituted. But note that -o is still 0.
- (2) The slice of *s* from *i* to *j* is defined as the sequence of items with index *k* such that i <= k < j. If *i* or *j* is greater than len(*s*), use len(*s*). If *j* is omitted, use len(*s*). If *i* is greater than or equal to *j*, the slice is empty.
- (3) For strings: x in s is True if x is a substring of s.
- (4) Raises a ValueError exception when x is not found in s (i.e. out of range).

## Operations on mutable sequences (type list)

## Operations on mutable sequences

Operation	Result	Notes
s[i] = x	item $i$ of $s$ is replaced by $x$	
s[i:j[:step]] = t	slice of $s$ from $i$ to $j$ is replaced by $t$	
$\mathbf{del}\ s[i:j[:step]]$	same as $s[i:j] = []$	
$s.\mathbf{append}(x)$	same as s[len(s):len(s)] = [x]	(6)
s. <b>extend</b> $(x)$	same as $s[len(s):len(s)] = x$	(5)(6)
$s.\mathbf{count}(x)$	returns number of is for which $s[i] = x$	
s.index(x[, start[, stop]])	returns smallest i such that $s[i] = x$ . start and stop limit search to only part of	(1)
	the list.	
s.insert(i, x)	same as $s[i:i] = [x]$ if $i > 0$ . $i = -1$ inserts <b>before</b> the last element.	
$s.\mathbf{remove}(x)$	same as del $s[s.index(x)]$	(1)
$s.\mathbf{pop}([i])$	same as $x = s[i]$ ; del $s[i]$ ; return $x$	(4)
s.reverse()	reverses the items of s in place	(3)
s. <b>sort</b> ([cmp])	sorts the items of s in place	(2), (3)
$s.\mathbf{sort}([\mathtt{cmp} = cmpFunc])$		
[, key = keyGetter]		
[, reverse=bool])		

#### Notes:

- (1) Raises a ValueError exception when x is not found in s (i.e. out of range).
- (2) The sort() method takes an optional argument cmp specifying a comparison function taking 2 list items and returning -1, 0, or 1 depending on whether the 1st argument is considered smaller than, equal to, or larger than the 2nd argument. Note that this slows the sorting process down considerably. Since 2.4, 2 optional keywords args are added: key is a function of one argument that used to extract a comparison key from each list element (faster than cmp). Also, see attracter and itemgetter in the operator module. reverse: If True, reverse the sense of the comparison used. Since Python 2.3, the sort is guaranteed "stable". This means that two entries with equal keys will be returned in the same order as they were input. For example, you can sort a list of people by name, and then sort the list by age, resulting in a list sorted by age where people with the same age are in name-sorted order.
- (3) The sort () and reverse () methods **modify** the list **in place** for economy of space when sorting or reversing a large list. They don't return the sorted or reversed list to remind you of this side effect.
- (4) The pop() method is not supported by mutable sequence types other than lists. The optional argument i defaults to -1, so that by default the last item is removed and returned.
- (5) Raises a TypeError when x is not a list object.
- (6) append vs. extend: append takes any object and places as last element in list, while extend only takes a iterable object and extends the list with each element in x.

## Operations on mappings / dictionaries (type dict)

Operations	on mappings
Operation	

Operation	Result	Notes
len(d)	The number of items in d	
dict()	Creates an empty dictionary.	
<pre>dict(**kwargs)</pre>	Creates a dictionary init with the keyword args kwargs.	
dict(iterable)	Creates a dictionary init with (key, value) pairs provided by iterable.	
dict(d)	Creates a dictionary which is a copy of dictionary d.	
d.fromkeys(iterable, value=None)	Class method to create a dictionary with keys provided by iterator, and	
	all values set to <i>value</i> .	
d[k]	The item of $d$ with key $k$	(1)
d[k] = x	Set $d[k]$ to $x$	
$\mathbf{del}\ d[k]$	Removes $d[k]$ from $d$	(1)
d.clear()	Removes all items from $d$	
$d.\mathbf{copy}()$	A shallow copy of $d$	
$d.\mathbf{has}_{\mathbf{key}}(k)$	True if $d$ has key $k$ , else False	
k in d		
d.items()	A copy of d's list of (key, item) pairs	(2)
$d.\mathbf{keys}()$	A copy of <i>d</i> 's list of keys	(2)
$d1.\mathbf{update}(d2)$	for k, v in $d2.items(): d1[k] = v$	
	Since 2.4, <b>update</b> (**kwargs) and <b>update</b> (iterable) may also be used.	
d.values()	A copy of d's list of values	(2)

$d.\mathbf{get}(k [, d\epsilon faultval])$	The item of $d$ with key $k$	(3)
$d.$ <b>setdefault</b> $(k[,d\epsilon faultval])$	d[k] if k in d, else defaultval (and inserts it)	(4)
d.iteritems()	Returns an iterator over (key, value) <b>pairs</b> .	
d.iterkeys()	Returns an iterator over the mapping's keys.	
d.itervalues()	Returns an iterator over the mapping's values.	
$d.\mathbf{pop}(k[,d\epsilon fault])$	Removes key $k$ and returns the corresponding value. If key is not found,	
	default is returned if given, otherwise KeyError is raised.	
d.popitem()	Removes and returns an arbitrary (key, value) pair from d	
d.viewitems()	Returns a view object of the (key, value) pairs	(5)
d.viewkeys()	Returns a view object of the mappings keys	(5)
d.viewvalues()	Returns a view object of the mappings values	(5)

#### Notes:

- TypeError is raised if key is not acceptable.
- (1) KeyError is raised if key k is not in the map.
- (2) Keys and values are listed in random order.
- (3) Never raises an exception if *k* is not in the map, instead it returns *defaultval*. *defaultval* is optional, when not provided and *k* is not in the map, None is returned.
- (4) Never raises an exception if *k* is not in the map, instead returns *defaultVal*, and adds *k* to map with value *defaultVal*. *defaultVal* is optional. When not provided and *k* is not in the map, None is returned and added to map.
- (5) A *view object* provides a dynamic view on the dictionary's entries, which means that when the dictionary changes, the view reflects these changes. A view object is also iterable.

## Operations on strings (types str & unicode)

These string methods largely (but not completely) supersede the functions available in the string module. The str and unicode types share a common base class basestring.

Operations on strings		
Operation	Result	Notes
s.capitalize()	Returns a copy of $s$ with its first character capitalized, and the rest of the characters lowercased.	
s.center(width[, fillChar=''])	Returns a copy of <i>s</i> centered in a string of length <i>width</i> , surrounded by the appropriate number of <i>fillChar</i> characters.	(1)
s.count(sub[, start[, end]])	Returns the number of occurrences of substring <i>sub</i> in string <i>s</i> .	(2)
s.decode([encoding[, errors]])	Returns a unicode string representing the decoded version of str s, using the given codec (encoding). Useful when reading from a file or a I/O function that handles only str. Inverse of encode.	(3)
s. <b>encode</b> ([encoding[, errors]])	Returns a str representing an encoded version of s. Mostly used to encode a unicode string to a str in order to print it or write it to a file (since these I/O functions only accept str), e.g. u'légère'.encode('utf8'). Also used to encode a str to a str, e.g. to zip (codec 'zip') or uuencode (codec 'uu') it. Inverse of	(3)
s.endswith(suffix [, start[, end]])	decode.  Returns True if s ends with the specified suffix, otherwise return false. Since 2.5 suffix can also be a <b>tuple</b> of strings to try.	(2)
s.expandtabs([tabsize])	Returns a copy of s where all tab characters are expanded using spaces.	(4)
s.find(sub [,start[,end]])	Returns the lowest index in $s$ where substring $sub$ is found. Returns -1 if $sub$ is not found.	(2)
s.format(*args, *kwargs)	Returns s after replacing numeric and named formatting references found in braces (). (details)	
s.index(sub[, start[, end]])	like <b>find()</b> , but raises ValueError when the substring is not found.	(2)
s.isalnum()	Returns True if all characters in s are alphanumeric, False otherwise.	(5)
s.isalpha()	Returns True if all characters in s are alphabetic, False otherwise.	(5)
s.isdigit()	Returns True if all characters in s are digit characters, False otherwise.	(5)
s.islower()	Returns True if all characters in s are lowercase, False otherwise.	(6)
s.isspace()	Returns True if all characters in s are whitespace characters, False otherwise.	(5)
s.istitle()	Returns True if string $s$ is a titlecased string, False otherwise.	(7)
s.isupper()	Returns True if all characters in s are uppercase, False otherwise.	(6)
separator. <b>join</b> (seq)	Returns a concatenation of the strings in the sequence $seq$ , separated by string $separator$ , e.g.: ", ".join(['A', 'B', 'C']) -> "A,B,C"	
s.ljust/rjust/center(width[, fillChar=''])	Returns $s$ left/right justified/centered in a string of length $width$ .	(1), (8)
s.lower()	Returns a copy of s converted to lowercase.	
s. <b>lstrip</b> ([chars] )	Returns a copy of s with leading chars (default: blank chars) removed.	
s.partition(separ)	Searches for the separator <i>separ</i> in <i>s</i> , and returns a tuple (head, sep, tail) containing the part before it, the separator itself, and the part after it. If the separator is not found, returns ( <i>s</i> , ", ").	
s.replace(old, new[, maxCount = -1])	Returns a copy of s with the first maxCount (-1: unlimited) occurrences of substring old replaced by new.	(9)
s.rfind(sub[ , start[, end]])	Returns the highest index in $s$ where substring $sub$ is found. Returns -1 if $sub$ is not found.	(2)
c rinder(cuhl ctart[ ond]])	like $\mathbf{rfind}\Omega$ but raises $\mathtt{ValueError}$ when the substring is not found	(0)

s.rpartition(separ)	Searches for the separator separ in s, starting at the end of s, and returns a tuple (head, sep, tail) containing the (left) part before it, the separator itself, and the (right) part after it. If the separator is not found, returns (", ", s).	(4)
s.rstrip([chars])	Returns a copy of s with trailing chars(default: blank chars) removed, e.g. aPath.rstrip('/') will remove the trailing '/'from aPath if it exists	
s.split([separator[, maxsplit]])	Returns a list of the words in s, using separator as the delimiter string.	(10)
s.rsplit([separator[, maxsplit]])	Same as split, but splits from the end of the string.	(10)
s.splitlines([ keepends])	Returns a list of the lines in s, breaking at line boundaries.	(11)
s.startswith(prefix [, start[, end]])	Returns True if s starts with the specified prefix, otherwise returns False.  Negative numbers may be used for start and end. Since 2.5 prefix can also be a tuple of strings to try.	(2)
s. <b>strip</b> ([chars])	Returns a copy of s with leading and trailing chars (default: blank chars) removed.	
s.swapcase()	Returns a copy of s with uppercase characters converted to lowercase and vice versa.	
s.title()	Returns a titlecased copy of s, i.e. words start with uppercase characters, all remaining cased characters are lowercase.	
s.translate(table[, deletechars="])	Returns a copy of s mapped through translation table table. Characters from deletechars are removed from the copy prior to the mapping. Since 2.6 table may also be None (identity transformation) - useful for using translate to <b>delete</b> chars only.	(12)
s.upper()	Returns a copy of s converted to uppercase.	
s. <b>zfill</b> (width)	Returns the numeric string left filled with zeros in a string of length width.	

#### Notes:

- (1) Padding is done using spaces or the given character.
- (2) If optional argument *start* is supplied, substring *s*[*start*:] is processed. If optional arguments *start* and *end* are supplied, substring *s*[*start*:*end*] is processed.
- (3) Default encoding is sys.getdefaultencoding(), can be changed via sys.setdefaultencoding(). Optional argument errors may be given to set a different error handling scheme. The default for errors is 'strict', meaning that encoding errors raise a ValueError. Other possible values are 'ignore' and 'replace'. See also module codecs.
- (4) If optional argument tabsize is not given, a tab size of 8 characters is assumed.
- (5) Returns False if string s does not contain at least one character.
- (6) Returns False if string s does not contain at least one cased character.
- (7) A titlecased string is a string in which uppercase characters may only follow uncased characters and lowercase characters only cased ones.
- (8) *s* is returned if *width* is less than **len(s)**.
- (9) If the optional argument maxCount is given, only the first maxCount occurrences are replaced.
- (10) If separator is not specified or None, any whitespace string is a separator. If maxsplit is given, at most maxsplit splits are done.
- (11) Line breaks are not included in the resulting list unless keepends is given and true.
- (12) table must be a string of length 256.

## String formatting with the % operator

formatString % args --> evaluates to a string

• formatString mixes normal text with C printf format fields :

%[flag][width][.precision] formatCode

where *formatCode* is one of c, s, i, d, u, o, x, X, e, E, f, g, G, r, % (see table below).

- The *flag* characters -, +, blank, # and o are understood (see table below).
- Width and precision may be a \* to specify that an integer argument gives the actual width or precision. Examples of width and precision:

#### **Examples**

```
Format string
                       Result
'%3d' % 2
                        ' 2'
'%*d' % (3, 2)
                        ' 2'
'%-3d' % 2
                       12 1
'%03d' % 2
                       '002'
'% d' % 2
                        ' 2'
'%+d' % 2
                        '+2'
'%+3d' % -2
                        ' -2'
                       ' 2 '
'%- 5d' % 2
'%.4f' % 2
                       '2.0000'
'%.*f' % (4, 2)
                       '2.0000'
'%0*.*f' % (10, 4, 2) '00002.0000'
'%10.4f' % 2
                        ' 2.0000'
'%010.4f' % 2
                       '00002.0000'
```

- %s will convert any type argument to string (uses str() function)
- args may be a single arg or a tuple of args

```
'%s has %03d quote types.' % ('Python', 2) == 'Python has 002 quote types.'
```

• Right-hand-side can also be a *mapping*:

```
a = '%(lang)s has %(c)03d quote types.' % {'c':2, 'lang':'Python'}
```

(vars () function very handy to use on right-hand-side)

#### Format codes

Code Meaning

- d Signed integer decimal.
- i Signed integer decimal.
- o Unsigned octal.
- u Unsigned decimal.
- x Unsigned hexadecimal (lowercase).
- X Unsigned hexadecimal (uppercase).
- e Floating point exponential format (lowercase).
- E Floating point exponential format (uppercase).
- f Floating point decimal format.
- F Floating point decimal format.
- g Same as "e" if exponent is greater than -4 or less than precision, "f" otherwise.
- G Same as "E" if exponent is greater than -4 or less than precision, "F" otherwise.
- c Single character (accepts integer or single character string).
- r String (converts any python object using repr()).
- s String (converts any python object using str()).
- % No argument is converted, results in a "%" character in the result. (The complete specification is %%.)

### Conversion flag characters

Flag Meaning

- # The value conversion will use the "alternate form".
- o The conversion will be zero padded.
- The converted value is left adjusted (overrides "-").

(a space) A blank should be left before a positive number (or empty string) produced by a signed conversion.

+ A sign character ("+" or "-") will precede the conversion (overrides a "space" flag).

#### String templating

Since 2.4 [PEP 292] the string module provides a new mechanism to substitute variables into *template* strings. Variables to be substituted begin with a \$. Actual values are provided in a dictionary via the substitute or safe\_substitute methods (substitute throws KeyError if a key is missing while safe substitute ignores it):

```
t = string. Template ('Hello $name, you won \$\$ $amount') # (note $$ to literalize $) t.substitute ({'name': 'Eric', 'amount': 100000}) # -> u'Hello Eric, you won $100000'
```

### String formatting with format()

Since 2.6 [PEP 3101] string formatting can also be done with the format() method:

```
"string-to-format".format(args)
```

Format fields are specified in *string-to-format*, surrounded by {}, while actual values are args to format():

 $\{[\mathit{field}][!\mathit{conversion}][:\mathit{format\_spec}]\}$ 

- Each *field* refers to an arg either by its position (>=0), or by its name if it's a *keyword* argument. If left out, automatic numbering is used, so the first {...} specifier will use the first argument, the next specifier will use the next argument, and so on. Autonumbering cannot be mixed with explicit numbering, but it can be mixed with named fields. The same arg can be referenced more than once.
- The conversion can be !s or !r to call str() or repr() on the field before formatting.
- The *format\_spec* takes the following form:

[[fill]align][sign][#][o][width][,][.precision][type]

- The *align* flag controls the alignment when padding values (see table below), and can be preceded by a *fill* character. A fill cannot be used on its own.
- The *sign* flag controls the display of signs on numbers (see table below).
- $\bullet$  The # flag adds a leading 0b, 00, or 0x for binary, octal, and hex conversions.
- The o flag zero-pads numbers, equivalent to having a *fill-align* of o=.
- The *width* is a number giving the minimum field width. Padding will be added according to *align* until this width is

acmeveu.

- The , option indicates that commas should be included in the output as a thousands separator.
- For floating-point conversions, *precision* gives the number of places to display after the decimal point. For non-numeric conversion, *precision* gives the maximum field width.
- The *type* specifies how to present numeric types (see tables below).
- Braces can be doubled ({{ or }}}) to insert a literal brace character.

### Alignment flag characters

Flag Meaning

- < Left-aligns the field and pads to the right (default for non-numbers)
- > Right-aligns the field and pads to the left (default for numbers)
- = Inserts padding between the sign and the field (numbers only)
- Aligns the field to the center and pads both sides

## Sign flag characters

Flag Meaning

- + Displays a sign for all numbers
- Displays a sign for negative numbers only (default)
   (a space) Displays a sign for negative numbers and a space for positive numbers

#### Integer type flags

Flag Meaning

- b Binary format (base 2)
- c Character (interprets integer as a Unicode code point)
- d Decimal format (base 10) (default)
- o Octal format (base 8)
- x Hexadecimal format (base 16) (lowercase)
- X Hexadecimal format (base 16) (uppercase)

#### Floating-point type flags

Flag Meaning

- e Exponential format (lowercase)
- E Exponential format (uppercase)
- f Fixed-point format
- F Fixed-point format (same as "f")
- g General format same as "e" if exponent is greater than -4 or less than precision, "f" otherwise. (default)
- G General format Same as "E" if exponent is greater than -4 or less than precision, "F" otherwise.
- n Number format Same as "g", except it uses locale settings for separators.
- % Percentage Multiplies by 100 and displays as "f", followed by a percent sign.

For examples, see Format examples in the Python documentation.

## Operations on files (type file)

(Type file). Created with built-in functions open() [preferred] or its alias file(). May be created by other modules' functions as well

Unicode file names are now supported for all functions accepting or returning file names (open, os.listdir, etc...).

Operators on file objects

#### File operations

Operation	Result
f.close()	Close file $f$ .
f.fileno()	Get fileno (fd) for file f.
f.flush()	Flush file f's internal buffer.
f.isatty()	1 if file $f$ is connected to a tty-like dev, else 0.
f.next()	Returns the next input line of file f, or raises StopIteration when EOF is hit. Files are their own
	iterators. next is implicitly called by constructs like for line in f: print line.
f. <b>read</b> ([ $size$ ])	Read at most $size$ by tes from file $f$ and return as a string object. If $size$ omitted, read to EOF.
f.readline()	Read one entire line from file f. The returned line has a trailing \n, except possibly at EOF. Return "
	on EOF.
f.readlines()	Read until EOF with <b>readline</b> () and return a list of lines read.
f.xreadlines()	Return a sequence-like object for reading a file line-by-line without reading the entire file into
	memory. From 2.2, use rather: for line in f (see below).
<b>for</b> line <b>in</b> <i>f</i> : do something	Iterate over the lines of a file (using readline)
$f.\mathbf{seek}(offset[, whence=o])$	Set file <i>f</i> 's position, like "stdio's fseek()".

whence = 2 then offset relative to file end. f.tell() Return file f's current position (byte offset).

f.truncate([size]) Truncate fs size. If size is present, f is truncated to (at most) that size, otherwise f is truncated at

whence == 0 then use absolute indexing.whence == 1 then offset relative to current pos.

```
current position (which remains unchanged).

f.write(str) Write string to file f.
Write list of strings to file f. No EOL are added.

File Exceptions

EOFError
End-of-file hit when reading (may be raised many times, e.g. if f is a tty).

IOError
```

## Operation on sets (types set & frozenset) \_

Other I/O-related I/O operation failure

set and frozenset (immutable set). Sets are unordered collections of unique (non duplicate) elements. Elements must be hashable. frozensets are hashable (thus can be elements of other sets) while sets are not. All sets are *iterable*.

A set may be created with set (iterable) or curly brackets ({}), which also allows for list comprehensions, using curly brackets instead of square brackets.

Classes  ${\tt Sets}$  and  ${\tt ImmutableSet}$  in the module  ${\tt sets}$  is now deprecated.

Result

#### Main Set operations

Operation

oper action	REDUIT
<pre>set/frozenset([iterable=None])</pre>	[using built-in types] Builds a set or frozenset from the given iterable (default:
	empty), e.g. set([1,2,3]), set("hello").
len(s)	Cardinality of set s.
elt in s / not in s	True if element elt belongs / does not belong to set s.
for elt in s: process elt	Iterates on elements of set s.
s1.issubset(s2)	True if every element in s1 is in iterable s2.
s1.issuperset(s2)	True if every element in s2 is in iterable s1.
$s.\mathbf{add}(elt)$	Adds element elt to set s (if it doesn't already exist).
s. <b>remove</b> $(elt)$	Removes element elt from set s. KeyError if element not found.
s.discard(elt)	Removes element <i>elt</i> from set <i>s</i> if present.
$s.\mathbf{pop}()$	Removes and returns an arbitrary element from set s; raises KeyError if empty.
s.clear()	Removes all elements from this set (not on immutable sets!).
<i>s1.</i> <b>intersection</b> ( <i>s2</i> [, <i>s3</i> ]) or <i>s1&amp;s2</i>	Returns a new Set with elements <b>common</b> to all sets (in the method s2, s3, can be any iterable).
s1. <b>union</b> (s2[, s3]) or s1 s2	Returns a new Set with elements from <b>either</b> set (in the method s2, s3, can be any iterable).
s1.difference(s2[, s3]) or s1-s2	Returns a new Set with elements in $s_1$ but not in any of $s_2$ , $s_3$ (in the method $s_2$ , $s_3$ , can be any iterable)
s1.symmetric difference(s2) or s1^s2	Returns a new Set with elements in either s1 or s2 but not both.
s.copy()	Returns a shallow copy of set s.
s.update(iterable1[, iterable2])	Adds all values from all given iterables to set s.
1	

## Named Tuples \_

Python 2.6 module collections introduces the namedtuple datatype. The factory function namedtuple (typename, fieldnames) creates **subclasses** of tuple whose fields are accessible **by name** as well as **index**:

```
# Create a named tuple class 'person':
person = collections.namedtuple('person', 'name firstName age') # field names separated by space or comma
assert issubclass(person, tuple)
assert person._fields == ('name', 'firstName', 'age')

# Create an instance of person:
jdoe = person('Doe', 'John', 30)
assert str(jdoe) == "person(name='Doe', firstName='John', age=30)"
assert jdoe[0] == jdoe.name == 'Doe' # access by index or name is equivalent
assert jdoe[2] == jdoe.age == 30

# Convert instance to dict:
assert jdoe._asdict() == {'age': 30, 'name': 'Doe', 'firstName': 'John'}

# Although tuples are normally immutable, one can change field values via _replace():
jdoe._replace(age=25, firstName='Jane')
assert str(jdoe) == "person(name='Doe', firstName='Jane', age=25)"
```

#### Date/Time \_\_

Python has no intrinsic Date and Time types, but provides 2 built-in modules:

• time: time access and conversions

- datetime: classes date, time, datetime, timedelta, tzinfo.
- calendar: with functions such as isleap (year), leapdays (y1, y2) and weekday (year, month, day).

See also the third-party module: mxDateTime.

## **Advanced Types**

- See manuals for more details -
  - Module objects
  - Class objects
  - Class instance objects
  - Type objects (see module: types)
  - File objects (see abov e)
  - Slice objects
  - Ellips is object, used by extended slice notation (unique, named Ellipsis)
  - Null object (unique, named None)
  - XRange objects
  - Callable types:
    - User-defined (written in Python):
      - User-defined *Function* objects
      - lacktriangle User-defined Method objects
    - Built-in (written in C):
      - Built-in *Function* objects
      - Built-in *Method* object
  - Internal Types:
    - Code objects (byte-compile executable Python code: bytecode)
    - Frame objects (execution frames)
    - Traceback objects (stack trace of an exception)

## **Statements**

Statement	Result
pass	Null statement
del name[, name]*	Unbind <i>name</i> (s) from object. Object will be indirectly (and automatically) deleted only if no longer referenced.
<b>print</b> [>> fileobject,] [s1 [, s2 ]* [,]	Writes to sys.stdout, or to <i>fileobject</i> if supplied. Puts spaces between arguments. Puts newline at end unless statement ends with <b>comma</b> [if nothing is printed when using a comma, try calling sys.stdout.flush()]. Print is not required when running interactively, simply typing an expression will print its value, unless the value is None.
$\mathbf{exec} x [\mathbf{in} \ globals \ [, locals]]$	Executes <i>x</i> in namespaces provided. Defaults to current namespaces. <i>x</i> can be a string, open file-like object or a function object. <i>locals</i> can be any mapping type, not only a regular Python dict. See also built-in function execfile.
callable(value,[id=value],[*args], [**kw])	Call function callable with parameters. Parameters can be passed by name or be omitted if function defines default values. E.g. if callable is defined as "def callable (p1=1, p2=2)"
	"callable()" <= > "callable(1, 2)" "callable(10)" <= > "callable(10, 2)" "callable(p2=99)" <= > "callable(1, 99)"
	*args is a tuple of <b>positional</b> arguments.  **kw is a dictionary of <b>keyword</b> arguments.  See function definition.

## **Assignment operators**

## Assignment operators

Operator	Result	Notes
a = b	Basic assignment - assign object b to label a	(1)(2)
a += b	Roughly equivalent to $a = a + b$	(3)
a -= b	Roughly equivalent to $a = a - b$	(3)
a *= b	Roughly equivalent to $a = a * b$	(3)
a /= b	Roughly equivalent to $a = a / b$	(3)
a//=b	Roughly equivalent to $a = a // b$	(3)
a%=b	Roughly equivalent to $a = a \% b$	(3)
~ **_ L	Danahlar assistant to a sex h	(~)

```
a^{-}= 0
            Kougniy equivalent to a = a \cdot b
                                                              (3)
a \&= b
            Roughly equivalent to a = a \& b
                                                              (3)
a \mid = b
            Roughly equivalent to a = a \mid b
                                                              (3)
a = b
            Roughly equivalent to a = a \wedge b
                                                              (3)
a >>= b
            Roughly equivalent to a = a >> b
                                                              (3)
a \ll b
            Roughly equivalent to a = a << b
                                                              (3)
```

#### Notes:

• (1) Can unpack tuples, lists, and strings:

```
first, second = 1[0:2]
                             # equivalent to: first=1[0]; second=1[1]
  [f, s] = range(2)
                       # equivalent to: f=0; s=1
  c1, c2, c3 = 'abc'
                       # equivalent to: c1='a'; c2='b'; c3='c'
  (a, b), c, (d, e, f) = ['ab', 'c', 'def']
                                                 # equivalent to: a='a'; b='b'; c='c'; d='d'; e='e'; f='f'
Tip: x, y = y, x swaps x and y.
```

• (2) Multiple assignment possible:

```
a = b = c = 0
list1 = list2 = [1, 2, 3]
                             # list1 and list2 points to the same list (11 is 12)
```

(3) Not exactly equivalent - a is evaluated only once. Also, where possible, operation performed in-place - a is modified rather than replaced.

## **Conditional Expressions**

Conditional *Expressions* (not *statements*) have been added since 2.5 [PEP 308]:

```
result = (whenTrue if condition else whenFalse)
is equivalent to:
  if condition:
      result = whenTrue
      result = whenFalse
```

() are not mandatory but recommended.

#### **Control Flow statements**

#### Control flow statements

Statement

if condition: Usual if/else if/else statement. See also Conditional Expressions for one-line if-statements.

suite

[elif condition: suite]\*

[else: suite]

**while** condition: Usual while statement. The else suite is executed after loop exits, unless the loop is exited with

suite break.

[else: suite]

for element in sequence:

Iterates over sequence, assigning each element to element. Use built-in range or xrange function to

iterate a number of times. The else suite is executed at end unless loop exited with break.

Also see List comprehensions.

[else: suite] break

suite

Immediately exits for or while loop.

continue Immediately does next iteration of for or while loop.

return [result] Exits from function (or method) and returns result (use a **tuple** to return more than one value). If

no result given, then returns None.

yield expression (Only used within the body of a generator function, outside a try of a try..finally). "Returns" the

evaluated expression.

## **Exception statements**

## **Exception statements**

Statement Result expr is evaluated. if false, raises exception AssertionError with message. Before 2.3, assert expr[, message]

inhibited if \_\_debug\_\_ is o. try: Statements in block1 are executed. If an exception occurs, look in except clause(s) for

block1 matching exception(s). If matches or bare except, execute handler of that clause. If no exception happens. else-block in else clause is executed after block1. If exception has a

[except [exception [. value]]:

```
handler]+
[except [exception [as value]]:
 handler]+
[else:
 else-block]
try:
block1
finally:
final-block
trv:
 block1
[except [exception [, value]]:
handler1]+
[except [exception [as value]]:
handler]+
[else:
else-block]
finally:
final-block
with allocate-expression [as variable]:
with-block
with allocate-expression as variable [,
allocate-expression2 as variable2:
with-block
```

value, it is put in variable *value*. *exception* can also be a **tuple** of exceptions, e.g. except (KeyError, NameError), e: print e.

2.6 also supports the key word as instead of a comma between the exception and the value, which will become a mandatory change in Python 3.0 [PEP3110]. Statements in block1 are executed. If no exception, execute final-block (even if block1 is exited with a return, break or continue statement). If exception did occur, execute final-block and then immediately re-raise exception. Typically used to ensure that a resource (file, lock...) allocated before the try is freed (in the final-block) whatever the outcome of block1 execution. See also the with statement below. Unified try/except/finally. Equivalent to a try...except nested inside a try..finally [PEP341]. See also the with statement below.

Alternative to the try...finally structure [PEP343]. allocate-expression should evaluate to an object that supports the context management

protocol, representing a resource. This object may return a value that can optionally be bound to variable (variable is **not** assigned the result of expression).

The object can then run **set-up** code before with-block is executed and some **clean**-

The object can then run **set-up** code before with-block is executed and some **clear up** code is executed after the block is done, even if the block raised an exception. Standard Python objects such as files and locks support the context management protocol:

```
\begin{tabular}{ll} with open ('/etc/passwd', 'r') \begin{tabular}{ll} as f: \# file automatically closed on block exit for line in f: print line \end{tabular}
```

with threading.Lock(): # lock automatically released on block exit do something...

- You can write your own context managers.
- Helper functions are available in module contextlib.

In 2.5 the statement must be enabled by: from \_\_future\_\_ import with\_statement. The statement is always enabled starting in Python 2.6. Raises an instance of a class derived from BaseException (**preferred** form of raise). Raises exception of given class exceptionClass with optional value value. Arg traceback specifies a traceback object to use when printing the exception's backtrace.

A raise statement without arguments re-raises the last exception raised in the current function.

- An exception is an instance of an exception class.
- Exception classes must be derived from the predefined class: Exception, e.g.:

```
class TextException(Exception): pass
try:
    if bad:
       raise TextException()
except Exception:
    print 'Oops' # This will be printed because TextException is a subclass of Exception
```

- When an error message is printed for an unhandled exception, the class name is printed, then a colon and a space, and finally the instance converted to a string using the built-in function str().
- All built-in exception classes derives from StandardError, itself derived from Exception.
- [PEP 352]: Exceptions can now be **new-style classes**, and all built-in ones are. Built-in exception hierarchy slightly reorganized with the introduction of base class BaseException. Raising strings as exceptions is now deprecated (warning).

## **Name Space Statements**

raise exceptionInstance

traceback]]

raise

raise exceptionClass [, value [,

Imported module files must be located in a directory listed in the Python path (sys.path). Since 2.3, they may reside in a **zip** file [e.g. sys.path.insert(o, "aZipFile.zip")].

## Absolute/relative imports (since 2.5 [PEP328]):

- Feature must be enabled by: from \_\_future\_\_ import absolute\_import: will probably be adopted in 2.7.
- Imports are normally *relative*: modules are searched first in the current directory/package, and then in the builtin modules, resulting in possible ambiguities (e.g. masking a builtin symbol).
- When the new feature is enabled:

- import x will look up for module X in sys.path first (absolute import).
- import .x (with a dot) will still search for X in the current package first, then in builtins (relative import).
- import ... x will search for X in the package containing the current one, etc...

Packages (>1.5): a package is a name space which maps to a directory including module(s) and the special initialization module \_\_init\_\_.py (possibly empty).

Packages/directories can be nested. You address a module's symbol via [package.[package...].module.symbol.

[1.51: On Mac & Windows, the case of module file names must now match the case as used in the *import* statement]

#### Name space statements

Statement

Result

import module1 [as name1] [, module2]\*

Imports modules. Members of module must be referred to by qualifying with [package.]module name, e.g.:

```
import sys; print sys.argv
import package1.subpackage.module
package1.subpackage.module.foo()
```

module1 renamed as name1, if supplied.

from module import name1 [as othername1][, name2]\*

Imports names from module module in current namespace.

```
from sys import argv; print argv
from package1 import module; module.foo()
from package1.module import foo; foo()
```

name1 renamed as othername1, if supplied.

[2.4] You can now put parentheses around the list of names in a from module import names statement (PEP 328).

from module import \*

global name1 [, name2]

Imports all names in module, except those starting with "\_". Use sparsely, beware of name clashes!

```
from sys import *; print argv
from package.module import *; print x
```

Only legal at the top level of a module.

If *module* defines an \_\_all\_\_ attribute, only names listed in \_\_all\_\_ will be imported. NB: "from package import \*" only imports the symbols defined in the package's init .py file, not those in the package's modules!

Names are from global scope (usually meaning from module) rather than local (usually meaning only in function).

E.g. in function without global statements, assuming "x" is name that hasn't been used in function or module so far:

-Try to read from "x" -> NameError

- Try to write to "x" -> creates "x" local to function

If "x" not defined in function, but is in module, then: - Try to read from "x", gets value from module

- Try to write to "x", creates "x" local to function

But note "x[o]=3" starts with search for "x", will use to global "x" if no local "x".

## **Function Definition**

```
def funcName ([paramList]):
    suite
```

Creates a function object and binds it to name funcName.

```
paramList ::= [param [, param]*]
param ::= value | id=value | *id | **id
```

- Args are passed by "call-by-object-reference". This means, that mutable objects can be modified (ie. *inout* parameters), while immutable are passed by value (ie. *in* parameters).
- Use return to return (None) from the function, or return value to return value. Use a tuple to return more than one value, e.g. return 1,2,3
- Keyword arguments arg=value specify a default value (evaluated at function def. time). They can only appear last in the param list, e.g. foo(x, y=1, s='').
- Pseudo-arg \*args captures a tuple of all remaining non-keyword args passed to the function, e.g. if def foo(x, \*args): ... is called foo(1, 2, 3), then args will contain (2,3).
- Pseudo-arg \*\*kwargs captures a dictionary of all extra keyword arguments, e.g. if def foo(x, \*\*kwargs): ... is called

```
foo(1, y=2, z=3), then kwargs will contain {'y':2, 'z':3}. if def foo(x, *args, **kwargs): ... is called foo(1, 2, 3, y=4, z=5), then args will contain (2, 3), and kwargs will contain {'y':4, 'z':5}
```

- args and kwargs are conventional names, but other names may be used as well.
- \*args and \*\*kwargs can be "forwarded" (individually or together) to another function, e.g. def f1(x, \*args, \*\*kwargs):

```
f2(*args, **kwargs)
```

Since 2.6, \*\*kwargs can be any mapping, not only a dict.

• See also Anonymous functions (lambdas).

#### **Class Definition**

```
class className [(super_class1[, super_class2]*)]:
    suite
```

Creates a class object and assigns it name className.

suite may contain local "defs" of class methods and assignments to class attributes.

#### **Examples:**

```
class MyClass (class1, class2): ...
```

Creates a class object inheriting from both class1 and class2. Assigns new class object to name Myclass.

```
class MyClass: ...
```

Creates a base class object (inheriting from nothing). Assigns new class object to name MyClass. Since 2.5 the equivalent syntax class MyClass(): ... is allowed.

```
class MyClass (object): ...
```

Creates a *new-style* class (inheriting from object makes a class a *new-style* class -available since Python 2.2-). Assigns new class object to name MyClass.

- First arg to class instance methods (operations) is always the target instance object, called 'self by convention.
- Special static method \_\_new\_\_(cls[,...]) called when instance is created. 1st arg is a class, others are args to \_\_init\_\_(), more details here
- Special method \_\_init\_\_() is called when instance is created.
- Special method \_\_del\_\_() called when no more reference to object.
- Create instance by "calling" class object, possibly with arg (thus instance=apply(aClassObject, args...) creates an
  instance!)

## Example:

```
class c (c_parent):
    def __init__(self, name):
        self.name = name
    def print_name(self):
        print "I'm", self.name
    def call_parent(self):
        c_parent.print_name(self)

instance = c('tom')
print instance.name
'tom'
instance.print_name()
"I'm tom"
```

Call parent's super class by accessing parent's method directly and passing self explicitly (see call\_parent in example above). Many other special methods available for implementing arithmetic operators, sequence, mapping indexing, etc...

#### Types / classes unification

Base types int, float, str, list, tuple, dict and file now (2.2) behave like classes derived from base class object, and may be subclassed:

```
x = int(2) # built-in cast function now a constructor for base type
y = 3 # <=> int(3) (litterals are instances of new base types)
print type(x), type(y) # int, int
assert isinstance(x, int) # replaces isinstance(x, types.IntType)
```

```
assert issubclass(int, object) # base types derive from base class 'object'.
s = "hello" # <=> str("hello")
assert isinstance(s, str)

f = 2.3 # <=> float(2.3)
class MyInt(int): pass # may subclass base types
x,y = MyInt(1), MyInt("2")

print x, y, x+y # => 1,2,3

class MyList(list): pass

l = MyList("hello")

print l # ['h', 'e', 'l', 'l', 'o']
```

New-style classes extends object. Old-style classes don't.

#### Documentation Strings

Modules, classes and functions may be documented by placing a string literal by itself as the first statement in the suite. The documentation can be retrieved by getting the '\_\_doc\_\_' attribute from the module, class or function.

#### Example:

```
class C:
    "A description of C"
    def __init__(self):
        "A description of the constructor"
        # etc.

c.__doc__ == "A description of C".
c.__init__.__doc__ == "A description of the constructor"
```

#### Iterators

- An *iterator* enumerates elements of a *collection*. It is an object with a single method next() returning the next element or raising stopIteration.
- You get an iterator on obj via the new built-in function iter(obj), which calls obj.\_\_class\_\_.\_\_iter\_\_().
- A collection may be its **own** iterator by implementing both \_\_iter\_\_() and next().
- Built-in collections (lists, tuples, strings, dict) implement \_\_iter\_\_(); dictionaries (maps) enumerate their keys; files enumerates their lines.
- You can build a list or a tuple from an iterator, e.g. list (anIterator)
- Python implicitly uses iterators wherever it has to **loop**:

```
• for elt in collection:
```

- if elt in collection:
- when assigning tuples: x, y, z= collection

## **Generators**

- A generator is a function that retains its state between 2 calls and produces a **new** value at **each** invocation. The values are returned (one at a time) using the keyword yield, while return or raise StopIteration() are used to notify the end of values
- A typical use is the production of IDs, names, or serial numbers. Fancier applications like nanothreads are also possible.
- To **use** a generator: call the *generator function* to get a generator object, then call <code>generator.next()</code> to get the next value until <code>stopIteration</code> is raised.
- 2.4 introduces *generator expressions* [PEP 289] similar to list comprehensions, except that they create a generator that will return elements one by one, which is suitable for long sequences:

```
linkGenerator = (link for link in get_all_links() if not link.followed)
for link in linkGenerator:
    ...process link...
```

Generator expressions must appear between **parentheses**.

• [PEP342] Generators before 2.5 could only produce **output**. Now values can be **passed** to generators via their method send (value). yield is now an *expression* returning a value, so val = (yield i) will *yield* i to the caller, and will reciprocally evaluate to the value "sent" back by the caller, or None.

Two other new generator methods allow for additional control:

- throw(type, value=None, traceback=None) is used to raise an exception inside the generator (appears as raised by the yield expression).
- close () raises a new GeneratorExit exception inside the generator to terminate the iteration.
- Since 2.6 Generator objects have a gi code attribute that refers to the original code object backing the generator.

#### Example:

```
def genID(initialValue=0):
    v = initialValue
    while v < initialValue + 1000:
        yield "ID_%05d" % v
        v += 1
    return # or: raise StopIteration()

generator = genID() # Create a generator
for i in range(10): # Generates 10 values
    print generator.next()</pre>
```

## Descriptors / Attribute access \_

Descriptors are objects implementing at least the first of these 3 methods representing the descriptor protocol:

```
__get__(self, obj, type=None) --> value
__set__(self, obj, value)
__delete__(self, obj)
```

Python now transparently uses *descriptors* to describe and access the attributes and methods of new-style classes (i.e. derived from object).)

- Built-in descriptors now allow to define:
  - Static methods: Use staticmethod(f) to make method f(x) static (unbound), or (recommended) use decorator @staticmethod.
  - Class methods: like a static but takes the Class as 1st argument => Use f = classmethod(f) to make method f(theClass, x) a class method, or (recommended) use decorator @classmethod.
  - **Properties**: A property is an instance of the new built-in type property, which implements the descriptor protocol for attributes => Use propertyName = property(fget=None, fset=None, fdel=None, doc=None) to define a property inside or outside a class. Then access it as propertyName or obj.propertyName. Since 2.6, the new decorators @prop.getter, @prop.setter, and @prop.deleter add functions to an existing property:

```
class C(object):
    @property # (since Python 2.4)
    def x(self):
        return self._x

    @x.setter
    def x(self, value):
        self._x = value

    @x.deleter
    def x(self):
        del self._x
```

• **Slots**. New style classes can define a class attribute \_\_slots\_\_ to constrain the list of **assignable** attribute names, to avoid typos (which is normally not detected by Python and leads to the creation of new attributes), e.g. slots = ('x', 'y')

Note: According to recent discussions, the real purpose of slots seems still unclear (optimization?), and their use should probably be discouraged.

## Decorators for functions, methods & classes\_

• [PEP 318] A decorator D is noted @D on the line preceding the function/method it decorates:

```
def f(): ...
and is equivalent to:
    def f(): ...
    f = D(f)
```

thus, a decorator can be any function returning another function usually applied as a function transformation.

• Several decorators can be applied in cascade:

```
@A
    @B
    @C
    def f(): ...
is equivalent to:
    f = A(B(C(f)))
```

• A decorator is just a function taking the function to be decorated and returns the same function or some new callable thing.

Decorator functions can take arguments:

```
@A
    @B
    @C(args)
becomes:
    def f(): ...
    _deco = C(args)
    f = A(B( deco(f)))
```

- The decorators @staticmethod and @classmethod replace more elegantly the equivalent declarations f = staticmethod(f) and f = classmethod(f).
- [PEP 3129] Decorators may also be applied to classes:

```
class C(): ...
is equivalent to:
    class C(): ...
    C = D(C)
```

#### Some selected decorators

- @staticmethod makes a method static (unbound) from an instance.
- @classmethod A class method receives the class as implicit first argument, just like an instance method receives the instance.
- @prop.getter, @prop.setter and @prop.deleter Use a function for getting, setting or deleting the property prop

## **Misc**

```
lambda [param_list]: returnedExpr
```

Creates an anonymous function.

returnedExpr must be an expression, not a statement (e.g., not "if xx:...", "print xxx", etc.) and thus can't contain newlines. Used mostly for filter(), map(), reduce() functions, and GUI callbacks.

#### List comprehensions

## List comprehensions for dictionaries and sets

See also Generator expressions.

## **Built-In Functions**

Built-in functions are defined in a module builtin automatically imported.

#### **Built-In Functions**

Function

Result

\_import\_\_\_(name[,

globals[,locals[.from list]]])

abs(x)all(iterable) any(iterable)

apply(f, args[, kegwords])

basestring()

bin(x) $\mathbf{bool}([x])$ 

**buffer**(object[, ojfset[, size]])

bytearray(iterable) bytearray(length) bytes(object)

callable(x)chr(i)

classmethod(function)

 $\mathbf{cmp}(x,y)$  $\mathbf{coerce}(x,y)$ 

compile(string, filename, kind[, flags[, dont inherit]])

complex(real[, image])

**delattr**(obj, name) dict([mapping-or-sequence])

dir([object])

 $\mathbf{divmod}(a,b)$ enumerate(iterable[, start=0])

eval(s[, globals[, locals]])

Imports module within the given context (see library reference for more details)

Returns the absolute value of the number x.

Returns True if bool (x) is True for all values x in the iterable. Returns True if bool (x) is True for any value x in the iterable.

Calls func/method f with arguments args and optional keywords. Deprecated since 2.3, replace apply (func, args, keywords) with func (\*args, \*\*keywords) [details]

Abstract superclass of str and unicode; can't be called or instantiated directly, but useful in: isinstance(obj, basestring).

Converts a number to a binary string.

Converts a value to a Boolean, using the standard truth testing procedure. If x is false or omitted, returns False; otherwise returns True. bool is also a class/type, subclass of int. Class bool cannot be subclassed further. Its only instances are False and True. See also boolean operators Returns a Buffer from a slice of object, which must support the buffer call interface (string, array, buffer). Non essential function, see [details]

Constructs a mutable sequence of bytes. This type supports many of the same operations available in strs and lists. The latter form sets the size and initializes to all zero bytes. Constructs an 8-bit string representation of an object. Equivalent to str for now, but this can be used to explicitly indicate strings which should not be unicode when converting to Python 3.0 [PEP3112]

Returns True if x callable, else False.

Returns one-character string whose ASCII code is integer i.

Returns a class method for function. A class method receives the class as implicit first argument, just like an instance method receives the instance. To declare a class method, use this idiom:

```
class C:
   def f(cls, arg1, arg2, ...): ...
   f = classmethod(f)
```

Then call it on the class c.f() or on an instance c().f(). The instance is ignored except for its class. If a class method is called for a derived class, the derived class object is passed as the implied first argument.

Since 2.4 you can alternatively use the decorator notation:

```
class C:
   @classmethod
   def f(cls, arg1, arg2, ...): ...
```

Returns negative, o, positive if x < 0, y = 0, y = 0, respectively.

Returns a tuple of the two numeric arguments converted to a common type. Non essential function, see [details]

Compiles string into a code object. filename is used in error message, can be any string. It is usually the file from which the code was read, or e.g. '<string>' if not read from file. kind can be 'eval' if string is a single stmt, or 'single' which prints the output of expression statements that evaluate to something else than None, or be 'exec'. New args flags and dont inherit concern future statements. Since 2.6 the function accepts keyword arguments as well as positional parameters.

Creates a complex object (can also be done using J or j suffix, e.g. 1+3J). Since 2.6, also accepts strings, with or without parenthesis, e.g. complex('1+3J') or complex('(1+3J)').

Deletes the attribute named name of object obj <=> del obj.name

Returns a new dictionary initialized from the optional argument (or an empty dictionary if no argument). Argument may be a sequence (or anything iterable) of pairs (key, value).

Without args, returns the list of names in the current local symbol table. With a module, class or class instance object as arg, returns the list of names in its attr. dictionary. Since 2.6 object can override the std implementation via special method dir ().

Returns tuple (a//b, a%b)

Iterator returning pairs (index, item) from iterable, e.g. List (enumerate ('Py')) -> [(0, 'P'), (1, 'y')]. 2.6: Arg start specifies initial index value (default: 0).

Evaluates string s, representing a single python expression, in (optional) globals, locals contexts. s must have no NUL's or newlines. s can also be a code object. locals can be any mapping type, not only a regular Python dict.

Example:

```
x = 1; assert eval('x + 1') == 2
```

(To execute statements rather than a single expression, use Python statement exec or built-in function execfile) Executes a file without creating a new module, unlike import. locals can be any mapping type,

execfile(file[, globals[,locals]])

not only a regular Python dict.

Opens a file and returns a new file object. Alias for open.

Constructs a list from those elements of sequence for which function returns true. function takes one narameter

file(filename[,mode[,bifsize]]) **filter**(function, sequence)

one parameter. float(x)

Converts a number or a string to floating point. Since 2.6, x can be one of the strings 'nan', '+inf', or '-inf' to represent respectively IEEE 754 Not A Number, positive and negative

infinity. Use module math functions isnan() and isinf() to check for NAN or infinity.

Formats an object with the given specification (default ") by calling its format method. Returns a frozenset (immutable set) object whose (immutable) elements are taken from iterable, or empty by default. See also Sets.

getattr(object,name[,default])) Gets attribute called *name* from *object*, e.g. getattr(x, 'f') <=> x.f). If not found, raises AttributeError or returns default if specified.

Returns a dictionary containing the current global variables.

Returns true if *object* has an attribute called *name*. hash(object) Returns the hash value of the object (if it has one).

Invokes the built-in help system. No argument -> interactive help; if object is a string (name of a module, function, class, method, keyword, or documentation topic), a help page is printed on the console; otherwise a help page on *object* is generated.

Converts a number x to a hexadecimal string.

Returns a unique integer identifier for object. Since 2.5 always returns non-negative numbers. Prints prompt if given. Reads input and evaluates it. Uses line editing / history if module

readline available.

For un-evaluated input, see raw input.

Converts a number or a string to a plain integer. Optional base parameter specifies base from which to convert string values.

> Enters aString in the table of interned strings and returns the string. Since 2.3, interned strings are no longer 'immortal' (never garbage collected), see [details]

Returns true if otj is an instance of class classIrfo or an object of type classIrfo (classIrfo may

also be a **tuple** of classes or types). If issubclass (A,B) then is instance (x,A) = >isinstance(x,B)

Returns true if *class1* is derived from *class2* (or if *class1* is *class2*).

Returns an **iterator** on *obj*. If *sentinel* is absent, *obj* must be a collection implementing either iter\_\_() or \_\_getitem\_\_(). If sentinel is given, obj will be called with no arg; if the value returned is equal to sentinel, StopIteration will be raised, otherwise the value will be returned. See Iterators.

Returns the length (the number of items) of an object (sequence, dictionary, or instance of class implementing \_\_len\_\_).

Creates an empty list or a list with same elements as seq. seq may be a sequence, a container that supports iteration, or an iterator object. If seq is already a list, returns a shallow copy of it. Returns a dictionary containing current local variables.

Converts a number or a string to a long integer. Optional base parameter specifies the base from which to convert string values.

Returns a list of the results of applying function to each item from sequence(s). If more than one sequence is given, the function is called with an argument list consisting of the corresponding item of each sequence, substituting None for missing values when not all sequences have the same length. If function is None, returns a list of the items of the sequence (or a list of tuples if more than one sequence). => You might also consider using list comprehensions instead of map().

With a single argument iterable, returns the largest item of a non-empty iterable (such as a string, tuple or list). With more than one argument, returns the largest of the arguments. The optional key arg is a function that takes a single argument and is called for every value in the list.

With a single argument iterable, returns the smallest item of a non-empty iterable (such as a string, tuple or list). With more than one argument, returns the smallest of the arguments. The optional key arg is a function that takes a single argument and is called for every value in the list.

Returns the next item from iterator. If iterator exhausted, returns default if specified, or raises StopIteration otherwise.

Returns a new featureless object. object is the base class for all new style classes, its methods are common to all instances of new style classes.

Converts a number to an octal string.

Returns a new file object. See also alias file(). Use codecs.open() instead to open an encoded file and provide transparent encoding / decoding.

- filename is the file name to be opened
- *mode* indicates how the file is to be opened:
  - 'r' for reading
  - 'w' for writing (truncating an existing file)
  - 'a' opens it for appending
  - '+' (appended to any of the previous modes) open the file for updating (note that 'w+'truncates the file)
  - 'b' (appended to any of the previous modes) open the file in binary mode
  - 'U' (or 'rU') open the file for reading in *Universal New line mode*: all variants of EOL (CR, LF, CR+LF) will be translated to a single LF ( $\n$ ).
- bufsize is o for unbuffered, 1 for line buffered, negative or omitted for system default, >1

format(value[, format\_spec]) frozenset([iterable])

globals()

hasattr(object, name)

**help**([object])

hex(x)id(object)

issubclass(class1, class2)

iter(obj[,sentinel])

len(otj)

list([seq])

locals() long(x[,base])

map(function, sequence[, sequence, ...])

max(iterable[, key=func]) max(v1, v2, ...[, key=func])

**min**(*iterable*[, *key*=func]) min(v1, v2, ...[, key=func])

**next**(iterator[, default])

object()

oct(x)

**open**(filename [, mode='r', [*bufsize*]])

input([prompt])

int(x[,base])

intern(aString)

isinstance(otj, classIrfo)

for a buffer of (about) the given size. Returns integer ASCII value of c (a string of len 1). Works with Unicode char. Returns x to power y [modulo z]. See also \*\* operator. Returns a property attribute for new-style classes (classes deriving from object). fget, fset, and

```
ord(c)
pow(x, y[, z])
property([fget[, fset[, fdel[,
doc]]]])
```

fdel are functions to get the property value, set the property value, and delete the property, respectively. Typical use: class C(object): def \_\_init\_\_(self): self.\_\_x = None def getx(self): return self.\_

```
def setx(self, value): self.__x = value
def delx(self): del self. x
x = property(getx, setx, delx, "I'm the 'x' property.")
```

**print**(\**args* [, *sep=*''] [,  $end= \n'$ ] [, file= sy s.stdout]) When future .print function is active, the print statement is replaced by this function [PEP3105]. Each item in args is printed to file with sep as the delimiter, and finally followed by end.

#### Each of these statements:

```
print 'foo', 42
print 'foo', 42,
print >> sys.stderr 'warning'
can now be written in this functional form:
print('foo', 42)
```

```
print('foo', 42, end='')
print('warning', file=sys.stderr)
Returns list of ints from >= start and < end.
```

With 1 arg, list from 0..arg-1 With 2 args, list from start..end-1

With 3 args, list from start up to end by step

Prints prompt if given, then reads string from std input (no trailing \n). See also input(). Applies the binary function f to the items of list so as to reduce the list to a single value. If init is given, it is "prepended" to list.

Re-parses and re-initializes an already imported module. Useful in interactive mode, if you want to reload a module after fixing it. If module was syntactically correct but had an error in initialization, must import it one more time before calling reload().

Returns a string containing a printable and if possible evaluable representation of an object. <=> `object` (using backquotes). Class redefinable ( repr ). See also str()

Returns the floating point value x rounded to n digits after the decimal point.

Returns a set object whose elements are taken from iterable, or empty by default. See also Sets. This is the counterpart of getattr().setattr(o, 'foobar', 3) <=> o.foobar = 3. Creates attribute if it

Returns a *slice object* representing a range, with R/O attributes: start, stop, step.

Returns a **new** sorted list from the items in *iterable*. This contrasts with list.sort() that sorts lists in place and doesn't apply to immutable sequences like strings or tuples. See sequences.sort

Returns a static method for function. A static method does not receive an implicit first argument. To declare a static method, use this idiom:

```
class C:
   def f(arg1, arg2, ...): ...
   f = staticmethod(f)
```

Then call it on the class c.f() or on an instance c().f(). The instance is ignored except for its

Since 2.4 you can alternatively use the decorator notation:

```
class C:
   @staticmethod
   def f(arg1, arg2, ...): ...
```

Returns a string containing a nicely printable representation of an object. Class overridable (\_\_str\_\_). See also repr().

Returns the sum of a sequence of numbers (not strings), plus the value of parameter. Returns start when the sequence is empty.

Returns the superclass of type. If the second argument is omitted the super object returned is unbound. If the second argument is an object, is instance (obj, type) must be true. If the second argument is a type, issubclass (type2, type) must be true. Typical use: class C(B):

```
def meth(self, arg):
 super(C, self).meth(arg)
```

Creates an empty tuple or a tuple with same elements as seq. seq may be a sequence, a container that supports iteration, or an iterator object. If seq is already a tuple, returns itself (not a copy). Returns a type object [see module types] representing the type of obj. Example: import types if type(x) = types.StringType: print 'It is a string'. NB: it is better to use instead: if isinstance(x,

range([start,] end [, step])

raw\_input([prompt]) **reduce**(*f*, *list* [, *init*])

reload(module)

repr(object)

round(x, n=0)**set**([iterable]) setattr(object, name, value)

slice([start,] stop[, step])  ${f sorted}(iterable[, cmp[, key[,$ reverse]]])

staticmethod(function)

str(object)

sum(iterable[, start=0])

super( type[, object-or-type])

tuple([seq])

type(obj)

types.StringType)...

unichr(code) Returns a unicode string 1 char long with given code.

unicode(string[,Creates a Unicode string from a 8-bit string, using the given encoding name and error treatmentencoding[,error]]])('strict', 'ignore',or 'replace'). For objects which provide a \_\_unicode\_\_ () method, it will call this

method without arguments to create a Unicode string.

vars([object]) Without arguments, returns a dictionary corresponding to the current local symbol table. With

a module, class or class instance object as argument, returns a dictionary corresponding to the

object's symbol table. Useful with the "%" string formatting operator.

**xrange**(start [, end [, step]]) Like range(), but doesn't actually store entire list all at once. Good to use in "for" loops when there

is a big range and little memory.

zip(seq1[, seq2,...]) [No, that's not a compression tool! For that, see module zipfile] Returns a list of tuples where each

tuple contains the nth element of each of the argument sequences. Since 2.4 returns an empty

list if called with no arguments (was raising TypeError before).

## **Built-In Exception classes**

#### **BaseException**

Mother of all exceptions (was Exception before 2.5). New-style class. exception.args is a tuple of the arguments passed to the constructor. Since 2.6 the exception.message attribute is deprecated.

KeyboardInterrupt & SystemExit were moved out of Exception because they don't really represent errors, so now a try:...except Exception: will only catch errors, while a try:...except BaseException: (or simply try:..except:) will still catch everything.

#### • GeneratorExit

Raised by the close () method of generators to terminate the iteration. Before 2.6 was derived from Exception.

#### • KeyboardInterrupt

On user entry of the interrupt key (often `CTRL-C'). Before 2.5 was derived from Exception.

#### System Exit

On sys.exit(). Before 2.5 was derived from Exception.

## Exception

Base of all errors. Before 2.5 was the base of all exceptions.

#### • GeneratorExit

Moved under BaseException.

### StandardError

Base class for all built-in exceptions; derived from Exception root class.

### ArithmeticError

Base class for arithmetic errors.

## FloatingPointError

When a floating point operation fails.

#### OverflowError

On excessively large arithmetic operation.

#### ZeroDivisionError

On division or modulo operation with 0 as 2nd argument.

#### AssertionError

When an assert statement fails.

#### AttributeError

On attribute reference or assignment failure

#### EnvironmentError

On error outside Python; error arg. tuple is (errno, errMsg...)

#### IOError

I/O-related operation failure.

## OSError

Used by the os module's os.error exception.

### WindowsError

When a Windows-specific error occurs or when the error number does not correspond to an error value.

#### EOFError

Immediate end-of-file hit by input() or raw\_input()

#### ImportError

On failure of import to find module or name.

## KeyboardInterrupt

Moved under BaseException.

#### LookupError

base class for Index Error, Key Error

#### IndexError

On out-of-range sequence subscript

on out or range bequence bubberryt

#### KeyError

On reference to a non-existent mapping (dict) key

#### MemoryError

On recoverable memory exhaustion

#### NameError

On failure to find a local or global (unqualified) name.

#### UnboundLocalError

On reference to an unassigned local variable.

#### ReferenceError

On attempt to access to a garbage-collected object via a weak reference proxy.

#### RuntimeError

Obsolete catch-all; define a suitable error instead.

#### NotImplementedError

On method not implemented.

#### SyntaxError

On parser encountering a syntax error

#### IndentationError

On parser encountering an indentation syntax error

#### TabError

On improper mixture of spaces and tabs

#### System Error

On non-fatal interpreter error - bug - report it!

#### TypeError

On passing inappropriate type to built-in operator or function.

#### ValueError

On argument error not covered by TypeError or more precise.

#### UnicodeError

On Unicode-related encoding or decoding error.

#### UnicodeDecodeError

On Unicode decoding error.

#### UnicodeEncodeError

On Unicode encoding error.

#### UnicodeTranslateError

On Unicode translation error.

#### StopIteration

Raised by an iterator's <code>next()</code> method to signal that there are no further values.

#### • System Exit

 $Moved\ under\ {\tt BaseException.}$ 

#### Warning

Base class for warnings (see module warning)

## DeprecationWarning

Warning about deprecated code.

## FutureWarning

Warning about a construct that will change semantically in the future.

### ImportWarning

Warning about probable mistake in module import (e.g. missing init .py).

## OverflowWarning

Warning about numeric overflow. Won't exist in Python 2.5.

#### PendingDeprecationWarning

Warning about future deprecated code.

#### RuntimeWarning

Warning about dubious runtime behavior.

#### SyntaxWarning

Warning about dubious syntax.

#### • UnicodeWarning

When attempting to compare a Unicode string and an 8-bit string that can't be converted to Unicode using default ASCII encoding (raised a UnicodeDecodeError before 2.5).

#### UserWarning

Warning generated by user code.

## Standard methods & operators redefinition in classes

Standard methods & operators map to special methods '\_\_method\_\_' and thus can be **redefined** (mostly in user-defined classes), e.g.:

```
def __init__(self, v): self.value = v
  def __add__(self, r): return self.value + r

a = C(3) # sort of like calling C.__init__(a, 3)
a + 4 # is equivalent to a. add (4)
```

#### Special methods for any class

```
Method
                                    Description
__new__(cls[, ...])
                                     Instance creation (on construction). If __new__ returns an instance of cls then __init__ is
                                     called with the rest of the arguments (...), otherwise __init__ is not invoked. More details
   _init___(se.f, args)
                                     Instance initialization (on construction)
   _del__(sef)
                                     Called on object demise (refcount becomes o)
   _repr___(se.f)
                                     repr() and `...` conversions
   str__(se.f)
                                     str() and print statement
   _{\mathbf{sizeof}}__(se f)
                                     Returns amount of memory used by object, in bytes (called by sys.getsizeof()).
   _format__(sef, format_spec)
                                     format() and str.format() conversions
                                     Compares se f to other and returns <0, 0, or >0. Implements >, <, == etc...
   cmp (se t, other)
                                     [PEP357] Allows using any object as integer indice (e.g. for slicing). Must return a single
   _index__(sef)
                                     integer or long integer value.
   _lt___(se_f, other)
                                     Called for set < other comparisons. Can return anything, or can raise an exception.
                                     Called for set < other comparisons. Can return anything, or can raise an exception.
   _le__(se.f, other)
   _gt__(se f, other)
                                     Called for sef > other comparisons. Can return anything, or can raise an exception.
   _ge__(se f, other)
                                     Called for sef > = other comparisons. Can return anything, or can raise an exception.
   _eq__(se.f, other)
                                     Called for sef = other comparisons. Can return anything, or can raise an exception.
  _ne__(sef, other)
                                     Called for set != other (and set <> other) comparisons. Can return anything, or can raise an
                                     exception.
                                     Compute a 32 bit hash code; hash () and dictionary ops. Since 2.5 can also return a long
 __hash___(se f)
                                     integer, in which case the hash of that value will be taken. Since 2.6 can set hash = None
                                     to void class inherited hashability.
                                     Returns 0 or 1 for truth value testing, when this method is not defined, len () is called if
__nonzero__(sef)
                                     defined; otherwise all class instances are considered "true".
                                     Called when attribute lookup doesn't find name. See also __getattribute__.
   getattr__(sef,name)
   _getattribute__( se f, name)
                                     Same as __getattr__ but always called whenever the attribute name is accessed.
                                     Returns the list of names of valid attributes for the object. Called by builtin function dir(),
   _dir__( se_f)
                                     but ignored unless getattr or getattribute is defined.
                                     Called when setting an attribute (inside, don't use "se f.name = value", use instead
 __setattr___(sef, name, value)
                                     "se.f.\__dict\__[name] = value")
 __delattr__(sef, name)
                                     Called to delete attribute < name >.
  _call__(se.f, *args, **kwargs)
                                     Called when an instance is called as function: obj (arg1, arg2, ...) is a shorthand for
                                     obj. call (arg1, arg2, ...).
  _enter__(sef)
                                     For use with context managers, i.e. when entering the block in a with-statement. The with
                                     statement binds this method's return value to the as object.
   _exit___(se f, type, value,
                                     When exiting the block of a with-statement. If no errors occurred, type, value, traceback are
traceback)
                                     None. If an error occured, they will contain information about the class of the exception, the
                                     exception object and a traceback object, respectively. If the exception is handled properly,
                                     return True. If it returns False, the with-block re-raises the exception.
```

## Operators \_

See list in the operator module. Operator function names are provided with **2 variants**, with or without leading & trailing '\_\_' (e.g. \_\_add\_\_ or add).

#### Numeric operations special methods

                     __len__(self)
                                                      length of object, >= o. Length o == false
                                                      Get element at indice /key k (indice starts at o). Or, if k is a slice object, return
                     \underline{\underline{getitem}}(self, k)
  self[k]
                     __missing__(self, key)
                                                      Hook called when key is not found in the dictionary, returns the default value.
  self[k] = value
                     __setitem__(self, k, value)
                                                      Set element at indice/key/slice k.
                                                      Delete element at indice/key/slice k.
  del self[k]
                        _{\mathbf{delitem}}_{\mathbf{(}}self, k)
  elt in self
                                                      More efficient than std iteration thru sequence.
                       _contains__(self, elt)
  elt not in self
                     not __contains__(self, elt)
  iter(self)
                     __iter__(self)
                                                      Returns an iterator on elements (keys for mappings <=> self.iterkeys()). See
                                                      iterators.
  Sequences, general methods, plus:
                                                      Deprecated since 2.0, replaced by getitem with a slice object as
  self[i:j]
                     \underline{\underline{getslice}} (self, i, j)
                                                      parameter.
                                                      Deprecated since 2.0, replaced by setitem with a slice object as
  self[i:j] = seq
                     __setslice__(self, i, j, seq)
                                                      parameter.
  del self[i:j]
                                                      Same as self[i:j] = [] - Deprecated since 2.0, replaced by delitem with a
                     \underline{\mathbf{delslice}}_{(self, i, j)}
                                                      slice object as parameter.
  self* n
                                                      (__repeat__ in the official doc but doesn't work!)
                        _mul___(self, n)
  self + other
                     __add__(self, other)
                                                        _concat__ in the official doc but doesn't work!)
  Mappings, general methods, plus:
  hash(self)
                     __hash__(self)
                                                      hashed value of object self is used for dictionary keys
```

## Special informative state attributes for some types:

**Tip**: use module inspect to inspect live objects.

#### Lists & Dictionaries

Attribute Meaning
\_\_methods\_\_ (list, R/O): list of method names of the object Deprecated, use dir() instead

## Modules

Attribute Meaning

```
(string/None, R/O): doc string (<=> __dict__['__doc__'])
  _doc__
   name
                 (string, R/O): module name (also in __dict__['__name__'])
   package
                (string/None, R/W): If defined, package name used for relative imports (also in __dict__['__package__']).
                 [PEP366].
                 (dict, R/O): module's name space
   dict
  file
                 (string/undefined, R/O): pathname of .pyc, .pyo or .pyd (undef for modules statically linked to the interpreter).
                 (list/undefined, R/W): List of directory paths where to find the package (for packages only).
  _path__
 Classes
Attribute

  members
 Codes
Attribute
                    Meaning
                    (string, R/O): function name
co name
                    (int, R/o): number of positional args
co_argcount
                    (int, R/O): number of local vars (including args)
co nlocals
                    (tuple, R/O): names of local vars (starting with args)
co_varnames
                    (string, R/O): sequence of by tecode instructions
co code
                    (tuple, R/O): literals used by the bytecode, 1st one is function doc (or None)
co_consts
                    (tuple, R/O): names used by the bytecode
co names
                    (string, R/O): filename from which the code was compiled
co filename
co firstlineno
                    (int, R/O): first line number of the function
                    (string, R/O): string encoding by tecode offsets to line numbers.
co lnotab
co stacksize
                    (int, R/O): required stack size (including local vars)
                    (int, R/O): flags for the interpreter bit 2 set if function uses "*arg" syntax, bit 3 set if function uses
co_flags
                     '**key words' sy ntax
 Frames
Attribute
f back
                    (frame/None, R/O): previous stack frame (toward the caller)
```

(code, R/O): code object being executed in this frame

f code

f locals (dict, R/O): local vars f globals (dict, R/O): global vars

(dict, R/O): built-in (intrinsic) names f builtins

f restricted (int, R/O): flag indicating whether function is executed in restricted mode

f lineno (int, R/O): current line number

(int, R/O): precise instruction (index into by tecode) f lasti

(function/None, R/W): debug hook called at start of each source line f\_trace

(Type/None, R/W): Most recent exception type f\_exc\_type (any, R/W): Most recent exception value f\_exc\_value

(traceback/None, R/W): Most recent exception traceback f\_exc\_traceback

#### Tracebacks

Attribute Meaning

tb\_next (frame/None, R/O): next level in stack trace (toward the frame where the exception occurred)

tb\_frame (frame, R/O): execution frame of the current level (int, R/O): line number where the exception occured tb lineno (int, R/O): precise instruction (index into by tecode) tb lasti

#### Slices

Attribute Meaning

(any/None, R/O): lowerbound, included start (any/None, R/O): upperbound, excluded stop

(any/None, R/O): step value step

## Complex numbers

Attribute Meaning

real (float, R/O): real part (float, R/O): imaginary part imag

#### xranges

Attribute Meaning

tolist (Built-in method, R/O):?

## **Important Modules**

System-specific parameters and functions.

## Some sys variables

Variable Content

The list of command line arguments passed to a Python script. sys.argv[0] is the script name. argv builtin\_module\_names A list of strings giving the names of all modules written in C that are linked into this interpreter.

Native byte order, either 'big'(-endian) or 'little'(-endian). byteorder

copyright A string containing the copy right pertaining to the Python interpreter.

dont write bytecode

exec\_prefix

If True, prevents Python from writing .pyc or .pyo files (same as invocation option -B). Root directory where platform-dependent Python files are installed, e.g. 'C:\\Python23', '/usr'.

prefix

executable Name of executable binary of the Python interpreter (e.g. 'C:\\Python23\\python.exe',

'/usr/bin/python')

User can set to a parameterless function. It will get called before interpreter exits. Deprecated since 2.4. exitfunc

Code should be using the existing atexit module

Status of command line flags, as a R/O struct. [details] flags

A structseq holding information about the float type (precision, internal representation, etc...). float info

last\_type, last\_value,

last traceback

Set only when an exception not handled and interpreter prints an error. Used by debuggers.

maxint Maximum positive value for integers. Since 2.2 integers and long integers are unified, thus integers

have no limit.

Largest supported code point for a Unicode character. maxunicode Dictionary of modules that have already been loaded. modules

path Search path for external modules. Can be modified by program. sys.path[0] == directory of script

currently executed.

platform The current platform, e.g. "sunos5", "win32"

Prompts to use in interactive mode, normally ">>>" and "..." ps1, ps2

stdin, stdout, stderr File objects used for I/O. One can redirect by assigning a new file object to them (or any object; with a

method write (string) for stdout/stderr, or with a method readline() for stdin).

stdin\_, stdout\_ and stderr\_ are the default values.

subversion Info about Python build version in the Subversion repository: tuple (interpreter-name, branch-name,

revision-range), e.g. ('CPython', 'tags/r25', '51908').

version String containing version info about Python interpreter.

version\_info Tuple containing Python version info - (major, minor, micro, level, serial).

version\_under used to form registry keys on Windows platforms (e.g. '2.2').

Some sys functions

Function Result

\_current\_frames() Returns the current stack frames for all running threads, as a dictionary mapping thread

identifiers to the topmost stack frame currently active in that thread at the time the function

is called.

display hook The function used to display the output of commands issued in interactive mode - defaults to

the builtin repr(). \_\_displayhook\_\_ is the original value.

excepthook Can be set to a user defined function, to which any uncaught exceptions are passed.

excepthook is the original value.

exit(n) Exits with status n (usually o means OK). Raises SystemExit exception (hence can be caught

and ignored by program)

setcheckinterval(interval) default: 10 until 2.2, 100 from 2.3).

getrefcount(object) Returns the reference count of the object. Generally 1 higher than you might expect, because

of *object* arg temp reference.

getsizeof(object[, default]) Returns the amount of memory used by object, in bytes. Calls o. sizeof () if available.

default returned if size can't be determined. [details]

settrace(func) Sets a trace function: called before each line of code is exited.

setprofile(*func*) Sets a profile function for performance profiling.

exc\_info() Info on exception currently being handled; this is a tuple (exc\_type, exc\_value,

exc\_traceback). Warning: assigning the traceback return value to a local variable in a

function handling an exception will cause a circular reference.

setdefaultencoding(encoding) Change default Unicode encoding - defaults to 7-bit ASCII.

getrecursionlimit() Retrieve maximum recursion depth.

setrecursionlimit() Set maximum recursion depth (default 1000).

#### OS

Miscellaneous operating system interfaces. Many functions, see the for a comprehensive list!

"synonym" for whatever OS-specific module (nt, mac, posix...) is proper for current environment. This module uses posix whenever possible.

See also M.A. Lemburg's utility platform.py (now included in 2.3+).

#### Some os variables

Variable Meaning

name of O/S-specific module (e.g. "posix", "mac", "nt")

path O/S-specific module for path manipulations.

On Unix, os.path.split() <=> posixpath.split() string used to represent current directory (eg '.')

curdir string used to represent current directory (eg '.') string used to represent parent directory (eg '..')

sep string used to separate directories ('/' or '\'). **Tip:** Use os.path.join() to build portable paths.

altsep Alternate separator if applicable (None otherwise)

pathsep character used to separate search path components (as in \$PATH), eg. ';' for windows. linesep line separator as used in **text** files, ie '\n' on Unix, '\r\n' on Dos/Win, '\r' on Mac.

## Some os functions

Function Result

 $makedirs(path[, mode=0777]) \\ Recursive directory creation (create required intermediary dirs); \\ os.error if fails.$ 

removedirs(path) Recursive directory delete (delete intermediary empty dirs); fails (os.error) if the

directories are not empty.

renames(old, new) Recursive directory or file renaming; os.error if fails. urandom(n) Returns a string containing n bytes of random data.

## posix\_

Posix OS interfaces.

Do not import this module directly, import os instead! (see also module: shutil for file copy & remove functions)

#### posix Variables

Variable Meaning

environ dictionary of environment variables, e.g. posix.environ['HOME'].

error exception raised on POSIX-related error.

Corresponding value is tuple of errno code and perror() string.

Some posix functions

Function Result

access(path, mode) Returns True if the requested access to path is granted. Use mode=F OK to check for existence, or an

OR-ed combination of R OK, W OK, and X OK to check for r, w, x permissions.

chdir(path) Changes current directory to path.

Changes the mode of path to the numeric mode chmod(path, mode) Closes file descriptor *fd* opened with posix.open. close(fd)

 $_{\text{exit}(n)}$ Immediate exit, with no cleanups, no System Exit, etc... Should use this to exit a child process.

execv(p, args)"Become" executable p with args args

Returns a string representing the current working directory. getcwd()

getcwdu() Returns a **Unicode** string representing the current working directory.

getpid() Returns the current process id. getsid() Calls the system call getsid() [Unix].

fork() Like C's fork(). Returns o to child, child pid to parent [Not on Windows].

kill(pid, signal) Like C's kill [Not on Windows].

listdir(path) Lists (base) names of entries in directory path, excluding '.' and '..'. If path is a Unicode string, so will

be the returned strings.

lseek(fd, pos, how) Sets current position in file td to position pos, expressed as an offset relative to beginning of file

(how=0), to current position (how=1), or to end of file (how=2).

Creates a directory named path with numeric mode (default 0777). Actual permissions = (mode & mkdir(path[, mode])

~umask & 0777). To set directly the permissions, use chmod() after dir creation.

Like C's open(). Returns file descriptor. Use file object functions rather than this low level ones. open(file, flags, mode)

Creates a pipe. Returns pair of file descriptors (r, w) [Not on Windows]. pipe()

popen(command, mode='r', Opens a pipe to or from command. Result is a file object to read to or write from, as indicated by bitSize=0)

mode being 'r' or 'w'. Use it to catch a command output ('r' mode), or to feed it ('w' mode).

remove(path)See unlink.

rename(old, new) Renames/moves the file or directory old to new. [error if target name already exists] renames(old, new) Recursive directory or file renaming function. Works like rename(), except **creation** of any

intermediate directories needed to make the new pathname good is attempted first. After the rename, directories corresponding to rightmost path segments of the old name will be pruned

away using removedirs().

rmdir(path) Removes the empty directory path

Reads n bytes from file descriptor td and return as string. read(td, n)

Returns st mode, st ino, st dev, st\_nlink, st\_uid,st\_gid, st\_size, st\_atime, st\_mtime, st\_ctime. stat(path)

[st ino, st uid, st gid are dummy on Windows]

system (command) Executes string command in a subshell. Returns exit status of subshell (usually o means OK). Since

2.4 use subprocess.call() instead.

Returns accumulated CPU times in sec (user, system, children's user, children's sys, elapsed real times()

time) [3 last not on Windows].

unlink(path) Unlinks ("deletes") the file (not dir!) path. Same as: remove.

utime(path, (aTime, mTime)) Sets the access & modified time of the file to the given tuple of values.

Waits for child process completion. Returns tuple of pid, exit status [Not on Windows]. wait()

Waits for process pid to complete. Returns tuple of pid, exit\_status [Not on Windows]. waitpid(pid, options)

walk(top[, topdown=True[, Generates a list of file names in a directory tree, by walking the tree either top down or bottom up. onerror=None[, For each directory in the tree rooted at directory top (including top itself), it yields a 3-tuple

followlinks=False]]]) (dirpath, dirnames, filenames) - more info here. See also os.path.walk().

2.6: New follow links parameter. If True, visit directories pointed to by links (beware of infinite

recursion!).

write(fd, str) Writes str to file fd. Returns nb of bytes written.

## posixpath\_

Posix pathname operations.

Do not import this module directly, import os instead and refer to this module as os.path. (e.g. os.path.exists(p))!

## posixpath functions

Function

abspath(path) Returns absolute path for *path*, taking current working dir in account.

commonprefix(list) Returns the longuest path prefix (taken character-by-character) that is a prefix of all paths in list (or "

if *list* empty).

dirname/basename(path) directory and name parts of path. See also split.

True if path is the path of an existing file or directory. See also lexists. exists(path)

expanduser(path) Returns a copy of *path* with "~" expansion done.

expandvars(path) Returns string that is (a copy of) path with environment vars \$name or \${name} expanded. [Windows:

case significant; must use Unix: \$var notation, not %var%; 2.6: Notation %name% also supported.]

Returns last access time of path (integer nb of seconds since epoch). getatime(path)

getctime(path) Returns the metadata change time of path (integer nb of seconds since epoch). Datuma last madification time of moth (interson what some de since anach)

getmtime(pain) Keturns last modification time of pain (integer no of seconds since epocn).
getsize(path) Returns the size in bytes of path. os.error if file inexistent or inaccessible.

isabs(path)
True if path is absolute.
isdir(path)
True if path is a directory.
isfile(path)
True if path is a regular file.
islink(path)
True if path is a symbolic link.

ismount(path) True if path is a mount point [true for all dirs on Windows].

join(p[,q[,...]]) Joins one or more path components in a way suitable for the current OS.

lexists(path) True if the file specified by path exists, whether or not it's a symbolic link (unlike exists).

normcase(path) Normalizes case of path. Has no effect under Posix. normpath(path) Normalizes path, eliminating double slashes, etc...

realpath(path) Returns the canonical path for path, eliminating any symbolic links encountered in the path. relpath(path[, start]) Returns a relative filepath to path, from the current directory by default, or from start if specified.

samefile( $f_1, f_2$ ) True if the 2 paths  $f_1$  and  $f_2$  reference the same file.

sam eopenfile  $(f_1, f_2)$  True if the 2 open file objects  $f_1$  and  $f_2$  reference the same file. sam estat  $(s_1, s_2)$  True if the 2 stat buffers  $s_1$  and  $s_2$  reference the same file.

split(p) Splits p into (head, tail) where tail is last pathname component and head is everything leading up to

that. <=> (dirname(p), basename(p))

 ${\rm splitdriv}\,{\rm e}(p) \hspace{1cm} {\rm Splits}\,{\rm path}\,p\,{\rm in}\,{\rm a}\,{\rm pair}\,({\rm 'driv}\,{\rm e}:',{\rm tail})\,[{\rm Windows}]$ 

splitext(p) Splits into (root, ext) where last comp of root contains no periods and ext is empty or starts with a

period. 2.6: Do not split on leading period.

walk(p, visit, arg) Calls the function visit with arguments (arg, dirname, names) for each directory recursively in the

directory tree rooted at p (including p itself if it's a dir). The argument dirname specifies the visited directory, the argument names lists the files in the directory. The visit function may modify names to influence the set of directories visited below dirname, e.g. to avoid visiting certain parts of the tree. **See** 

also os.walk() for an alternative.

### shutil

High-level file operations (copying, deleting).

#### Main shutil functions

Function copy (src, dest)

copy tree(src, dest[, symlinks=False

[, ignore=None]])

Copies the contents of file *src* to file *dest*, retaining file permissions.

Recursively copies an entire directory tree rooted at  $\mathit{src}$  into  $\mathit{dest}$  (which should not

already exist). If symlinks is true, links in src are kept as such in dest.

2.6: New *ignore* callable argument. Will be called with each directory path and a list of the directory's contents, must return a list of names to ignore.

shutil.ignore\_patterns() can be used to exclude glob-style patterns, e.g.:

shutil.copytree('projects/myProjUnderSvn', 'exportDir',
ignore=shutil.ignore\_patterns('\*~', '.svn'))

move(src, dest)

rmtree(path [, ignore\_errors

[, onerror]])

Recursively moves a file or directory to a new location.

Deletes an entire directory tree, ignoring errors if <code>ignore\_errors</code> is true, or calling <code>onerror(func, path, sys.exc\_info())</code> if supplied, with arguments <code>func</code> (faulty function),

and path (concerned file). This function fails when the files are Read Only.

make\_archive(base\_name, format [, root\_dir [, base\_dir [, verbose [, dry\_run [, owner [, group [, logger]]]]]]))

Create an archive file (eg. zip or tar) and returns its name. base\_name is the name of the file to create, including the path, minus any format-specific extension. format is the archive format: one of "zip", "tar", "bztar" or "gztar". root\_dir is a directory that will be the root directory of the archive; ie. we typically chdir into root\_dir before creating the archive. base\_dir is the directory where we start archiving from; ie. base\_dir will be the common prefix of all files and directories in the archive. root\_dir and base\_dir both default to the current directory. owner and group are used when creating a tar archive. By default, uses the current owner and group. logger is an instance of logging. Logger.

(and also: copyfile, copymode, copystat, copy2)

#### time \_\_

Time access and conversions.

(see also module mxDateTime if you need a more sophisticated date/time management)

#### Variables

Variable Meaning

altzone Signed offset of local DST timezone in sec west of the oth meridian.

day light Non zero if a DST timezone is specified.

timezone The offset of the local (non-DST) timezone, in seconds west of UTC.
tzname A tuple (name of local non-DST timezone, name of local DST timezone).

some june none Function Result On Unix: current processor time as a floating point number expressed in seconds. clock() On Windows: wall-clock seconds elapsed since the 1st call to this function, as a floating point number (precision  $< 1 \mu s$ ). time() Returns a float representing UTC time in **seconds** since the epoch. gmtime([secs]), Returns a 9-tuple representing time. Current time is used if secs is not provided. localtime([secs]) Since 2.2, returns a struct time object (still accessible as a tuple) with the following attributes: Index Attribute Values tm\_year Year (e.g. 1993) O tm\_mon Month [1,12] 1 tm mday Day [1,31] 2 3 tm hour Hour [0,23] tm min Minute [0,59] 4 5  $tm\_sec$ Second [0,61]; The 61 accounts for leap seconds and (the very rare) double leap seconds. 6 tm wday Weekday [0,6], Monday is o Julian day [1,366] 7 tm\_y day 8  $tm\_isdst$ Daylight flag: 0, 1 or -1; -1 passed to mktime () will usually work asctime([timeTuple]), 24-character string of the following form: 'Mon Apr 03 08:31:14 2006'. timeTuple defaults to localtime() if omitted. ctime([secs]) equivalent to asctime (localtime (secs)) mktime(timeTuple) Inverse of localtime(). Returns a float representing a number of seconds. strftime(format[, timeTuple]) **Formats** a time tuple as a string, according to *format* (see table below). Current time is used if timeTuple is omitted. strptime(string[, format]) Parses a string representing a time according to format (same format as for strftime(), see

below), default "%a %b %d %H:%M:%S %Y" = asctime format.

Suspends execution for secs seconds. secs can be a float.

Returns a time tuple/struct\_time.

## Formatting in stiftime() and strptime()

sleep(secs)

Directive Meaning %a Locale's abbreviated weekday name. %A Locale's full weekday name. Locale's abbreviated month name. %b Locale's full month name. %B 용C Locale's appropriate date and time representation. Day of the month as a decimal number [01,31]. %d Microsecond as a decimal number [0,999999], zero-padded on the left. %f %Н Hour (24-hour clock) as a decimal number [00,23]. Hour (12-hour clock) as a decimal number [01,12]. %Ι Day of the year as a decimal number [001,366]. %j Month as a decimal number [01,12]. %m 용M Minute as a decimal number [00,59]. gg Locale's equivalent of either AM or PM. Second as a decimal number [00,61]. Yes, 61! %S Week number of the year (Sunday as the first day of the week) as a decimal number [00,53]. All days in a new year %11 preceding the first Sunday are considered to be in week o. Weekday as a decimal number [o(Sunday),6]. %w %W Week number of the year (Monday as the first day of the week) as a decimal number [00,53]. All days in a new year preceding the first Sunday are considered to be in week o. Locale's appropriate date representation. %x %Х Locale's appropriate time representation. Year without century as a decimal number [00,99]. %y %Υ Year with century as a decimal number. Time zone name (no characters if no time zone exists). %Z UTC offset in the form + HHMM or -HHMM (empty string if the date is naive). % 7 응 응 A literal "%" character.

#### string

Common string operations.

As of Python 2.0, much (though not all) of the functionality provided by the string module have been superseded by built-in string methods.

Since 2.5 (?) all string module **methods** are considered **deprecated** => use built-in string methods instead.

digits
hexdigits, octdigits
letters, uppercase, lowercase, whitespace
ascii\_letters, ascii\_lowercase,
ascii\_uppercase

#### Some string functions

Function Result expandtabs(s, tabSize) Returns a copy of string s with tabs expanded. find/rfind(s, sub[, start=o[, end=o]) Returns the lowest/highest index in s where the substring sub is found such that sub is wholly contained in s[start:end]. Return -1 if sub not found. ljust/rjust/center(s, width[, fillChar='']) Returns a copy of string s; left/right justified/centered in a field of given width, padded with spaces or the given character. s is never truncated. lower/upper(s) Returns a string that is (a copy of) s in lowercase/uppercase. split(s[, sep=whitespace[, maxsplit=0]]) Returns a list containing the words of the string s, using the string sep as a separator. rsplit(s[, sep=whitespace[, maxsplit=o]]) Same as split above but starts splitting from the end of string, e.g. 'A,B,C'.split(',', 1) == ['A', 'B,C'] but 'A,B,C'.rsplit(',', 1) == ['A,B', 'C'] Concatenates a list or tuple of words with intervening separators; inverse of split. join(words[, sep='']) replace(s, old, new[, maxsplit=0] Returns a copy of string s with all occurrences of substring old replaced by new. Limits to maxsplit first substitutions if specified. strip(s[, chars = None])Returns a string that is (a copy of) s without leading and trailing chars (default: whitespace), if any. Also: 1strip, rstrip.

## re (sre)

Regular expression operations.

Handles Unicode strings. Implemented in new module **sre**, **re** now a mere front-end for compatibility. Patterns are specified as strings. Tip: Use **raw** strings (e.g. **r**'\w\*') to literalize backslashes.

## Regular expression syntax

Form	Description
	Matches any character (including newline if DOTALL flag specified).
^	Matches start of the string (of every line in MULTILINE mode).
\$	Matches end of the string (of every line in MULTILINE mode).
*	o or more of preceding regular expression (as <b>many</b> as possible).
+	1 or more of preceding regular expression (as many as possible).
?	o or 1 occurrence of preceding regular expression.
*?, +?, ??	Same as *, + and ? but matches as <b>few</b> characters as possible.
$\{m,n\}$	Matches from m ton repetitions of preceding RE.
$\{m,n\}$ ?	Idem, attempting to match as <b>few</b> repetitions as possible.
[]	Defines character set: e.g. '[a-zA-Z]' to match all letters (see also \w \S).
[^]	Defines complemented character set: matches if char is NOT in set.
\	Escapes special chars '*?+&\$ ()' and introduces special sequences (see below). Due to Python string rules, write as '\\'
	or r'\'in the pattern string.
//	Matches a litteral '\'; due to Python string rules, write as '\\\' in pattern string, or better using raw string: r'\\'.
	Specifies alternative: 'foo bar' matches 'foo' or 'bar'.
()	Matches any RE inside (), and delimits a group.
(?:)	Idem but doesn't delimit a group (non capturing parenthesis).
(?	Matches any RE inside (), and delimits a <b>named</b> group, (e.g. $r'(P[a-zA-Z_]\w^*)'$ defines a group named $id$ ).
P <name>)</name>	
(?P=name)	Matches whatever text was matched by the earlier group named name.
(?=)	Matches if matches next, but doesn't consume any of the string e.g. 'Isaac (?=Asimov)' matches 'Isaac' only if followed by 'Asimov'.
(?!)	Matches if doesn't match next. Negative of (?=).
(?<=)	Matches if the current position in the string is preceded by a match for that ends at the current position. This is called a <i>positive lookbehind assertion</i> .
(? )</td <td>Matches if the current position in the string is not preceded by a match for This is called a <i>negative lookbehind</i> assertion.</td>	Matches if the current position in the string is not preceded by a match for This is called a <i>negative lookbehind</i> assertion.
(?	[2.4+] group is either a numeric group ID or a group name defined with (?Pgroup) earlier in the expression. If
(group)A B)	the specified group matched, the regular expression pattern A will be tested against the string; if the group didn't
(24 )	match, the pattern B will be used instead.
(?#)	A comment; ignored.
(?letters)	letters is one or more of 'i', 'L', 'm', 's', 'u', 'x'. Sets the corresponding <b>flags</b> (re.I, re.L, re.M, re.S, re.U, re.X) for the entire RE. See the compile() function for equivalent flags.

Sequence Description Matches content of the *group* of the same number; groups are numbered starting from 1.  $\number$ Matches only at the start of the string. \A Empty str at beginning or end of word: "\bis\b' matches 'is', but not 'his'. \b Empty str NOT at beginning or end of word.  $\backslash B$ Any decimal digit ( $\langle = \rangle$  [0-9]). \d Any non-decimal digit char (<=> [ $^{\circ}$ 0-9]). \D Any whitespace char ( $<=> [ \t \n \r \]).$  $\backslash s$ \S Any non-whitespace char  $(<=> [^ \t\n\r\f\v]).$ Any alphaNumeric char (depends on LOCALE flag).  $\w$  $\backslash W$ Any non-alphaNumeric char (depends on LOCALE flag). Matches only at the end of the string.  $\backslash Z$ 

#### Variables

Variable Meaning

error Exception when pattern string isn't a valid regexp.

#### **Functions**

Function Result compile(pattern[,flags=0]) Compiles a RE pattern string into a regular expression object. Flags (combinable by |): I or IGNORECASE <=> (?i) case insensitive matching Lor LOCALE <=> (?L)make \w, \W, \b, \B dependent on the current locale  $M \ or \ MULTILINE <=> (?m)$ matches every new line and not only start/end of the whole string  $S \ or \ DOTALL <=> (?s)$ '.' matches ALL chars, including newline U or UNICODE <=> (?u)Make \w, \W, \b, and \B dependent on the Unicode character properties database.  $X \text{ or } VERBOSE \iff (?x)$ Ignores whitespace outside character sets Returns (a copy of) string with all non-alphanumerics backslashed. escape(string) If o or more chars at **beginning** of string matches the RE pattern string, returns a match(pattern, string[, flags]) corresponding MatchObject instance, or None if no match. search(pattern, string[, flags]) Scans thru string for a location matching pattern, returns a corresponding MatchObject instance, or None if no match. split(pattern, string[, maxsplit=0 Splits string by occurrences of pattern. If capturing () are used in pattern, then [, flags = o]])occurrences of patterns or subpatterns are also returned. findall(pattern, string) Returns a list of non-overlapping matches of pattern in string, either a list of groups or a list of tuples if the pattern has more than 1 group. Returns an iterator over all non-overlapping matches of pattern in string. For each match, finditer(pattern, string[, flags]) the iterator returns a match object. Empty matches are included in the result unless they touch the beginning of another match. Returns string obtained by replacing the (count first) leftmost non-overlapping sub(pattern, repl, string[, count=0 [, *flags*]]) occurrences of pattern (a string or a RE object) in string by repl; repl can be a string or a function called with a single MatchOtj arg, which must return the replacement string. subn(pattern, repl, string[, count=0 Same as sub(), but returns a tuple (newString, numberOfSubsMade).

## Regular Expression Objects

RE objects are returned by the compile function.

#### re object attributes

[, flags]])

Attribute Description

flags Flags arg used when RE obj was compiled, or o if none provided.

groupindex Dictionary of {group name: group number} in pattern.

pattern Pattern string from which RE obj was compiled.

#### re object methods

Method
match(string[, pos][, endpos])

Result

If zero or more characters at the beginning of string match this regular expression, returns a corresponding Matchobject instance. Returns None if the string does not match the pattern; note that this is different from a zero-length match.

The optional second parameter *pos* gives an index in the string where the search is to start; it defaults to o. This is not completely equivalent to slicing the string; the "pattern character

 matches at the real beginning of the string and at positions just after a newline, but not necessarily at the index where the search is to start.

The optional parameter *endpos* limits how far the string will be searched; it will be as if the string is endpos characters long, so only the characters from *pos* to *endpos* will be searched for a match.

search(string[, pos][, endpos])

Scans through string looking for a location where this regular expression produces a match, and returns a corresponding Matchobject instance. Returns None if no position in the string matches the pattern; note that this is different from finding a zero-length match at some point in the string.

The optional pos and endpos parameters have the same meaning as for the match () method.

split(string[, maxsplit=0]) Identical to the split() function, using the compiled pattern. Identical to the findall() function, using the compiled pattern. Identical to the finditer() function, using the compiled pattern. Identical to the sub() function, using the compiled pattern. Identical to the sub() function, using the compiled pattern. Identical to the sub() function, using the compiled pattern.

## Match Objects

Match objects are returned by the match & search functions.

#### Match object attributes

Attribute Description

pos Value of pos passed to search or match functions; index into string at which RE engine started search.

Value of endpos passed to search or match functions; index into string beyond which RE engine won't go.

re RE object whose match or search function produced this MatchObj instance.

string String passed to match () or search ().

#### Match object methods

MethodResultgroup([g1, g2, ...])Returns one or more groups of the match. If **one** arg, result is a string; if multiple args, result is a tuple with one item per arg. If gi is 0, returns the entire matching string; if 1 <= gi <= 99, returns string matching group #gi (or None if no such group); gi may also be a group name.groups()Returns a tuple of all groups of the match; groups not participating to the match have a value of None.Returns a string instead of tuple if len(tuple) == 1.start(group)Returns indices of start & end of substring matched by group (or None if group exists but didn't contribute to the match).span(group)Returns the 2-tuple (start(group), end(group)); can be (None, None) if group didn't contibute to the match

## Lexical scanners using regular expressions \_\_\_\_\_

There's an undocumented class in the re module called re. Scanner. The following recipee is from stackoverflow:

```
import re
 scanner=re.Scanner([
   (r"[0-9]+",
                          lambda scanner, token: ("INTEGER", token)),
   (r"[a-z_]+",
                        lambda scanner, token: ("IDENTIFIER", token)),
   (r"[,.]+",
                         lambda scanner, token: ("PUNCTUATION", token)),
   (r"\s+", None), # None == skip token.
 results, remainder=scanner.scan("45 pigeons, 23 cows, 11 spiders.")
 print results
which results in
 [('INTEGER', '45'),
  ('IDENTIFIER', 'pigeons'),
  ('PUNCTUATION', ','),
  ('INTEGER', '23'),
  ('IDENTIFIER', 'cows'),
  ('PUNCTUATION', ','),
  ('INTEGER', '11'),
  ('IDENTIFIER', 'spiders'),
  ('PUNCTUATION', '.')]
```

#### math\_

For complex number functions, see module cmath. For intensive number crunching, see Numerical Python and the Python and Scientific computing page.

**Constants** 

Name Value

pi 3.1415926535897931 e 2.7182818284590451

**Functions** 

Name Result

 $a\cos(x)$  Returns the arc cosine (measured in radians) of x.

a $\cosh(x)$  Returns the hyperbolic arc cosine (measured in radians) of x.

asin(x) Returns the arc sine (measured in radians) of x.

asinh(x) Returns the hyperbolic arc sine (measured in radians) of x.

atan(x) Returns the arc tangent (measured in radians) of x.

atan2(y, x) Returns the arc tangent (measured in radians) of y/x. The result is between -pi and pi. Unlike atan (y/x), the

signs of both x and y are considered.

atanh(x) Returns the hyperbolic arc tangent (measured in radians) of x.

ceil(x) Returns the ceiling of x as a float. This is the smallest integral value >= x.

copy sign(x, y) Copies the sign bit of an IEEE 754 number, returning the absolute value of x combined with the sign bit of y,

e.g. copysign(1, -0.0) returns-1.0.

cos(x) Returns the cosine of x (measured in radians).

cosh(x) Returns the hyperbolic cosine of x. degrees(x) Converts angle x from radians to degrees.

 $\operatorname{erf}(x)$  Return the error function at x.

 $\operatorname{erfc}(x)$  Return the complementary error function at x.

 $\exp(x)$  Returns e raised to the power of x.

exmp1(x) Return  $e^{**x} - 1$  with less loss of precision at small floats than exp(x) - 1.

fabs(x) Returns the absolute value of the float x.

factorial(n) returns n!

floor(x) Returns the floor of x as a float. This is the largest integral value <= x.

fmod(x, y) Returns fmod(x, y), according to platform C. x % y may differ.

frexp(x) Returns the mantissa and exponent of x, as pair (m, e). m is a float and e is an int, such that x = m \* 2.\*\*e. If

x is 0, m and e are both 0. Else 0.5 <= abs(m) < 1.0.

fsum(*iterable*) Returns an **accurate** floating point sum of values in *iterable* (assumes IEEE-754 floating point arithmetic).

 $\operatorname{gamma}(x)$  Return the Gamma function at x.

hypot(x, y) Returns the Euclidean distance sqrt (x\*x + y\*y). isinf(x) Returns True if x is infinite (positive or negative).

isnan(x) Returns True if x is not a number.

ldexp(x, i) x \* (2\*\*i)

lgamma(x) Return the natural logarithm of the absolute value of the Gamma function at x.

log(x[, base]) Returns the logarithm of x to the given base. If the base is not specified, returns the natural logarithm (base e)

of x.

 $\log_{10}(x)$  Returns the base 10 logarithm of x.

 $\log p(x)$  Returns the natural logarithm of 1+x (base e). The result is computed in a way which is accurate for x near

zero.

modf(x) Returns the fractional and integer parts of x. Both results carry the sign of x. The integer part is returned as a

float

pow(x, y) Returns  $x^*y$  (x to the power of y). Note that for y=2, it is more efficient to use  $x^*x$ .

radians(x) Converts angle x from degrees to radians.  $\sin(x)$  Returns the sine (measured in radians) of x.

sinh(x) Returns the hyperbolic sine of x.

 $\operatorname{sqrt}(x)$  Returns the square root of x.

tan(x) Returns the tangent (measured in radians) of x.

tanh(x) Returns the hyperbolic tangent of x.

trunc(x) Returns the Real value x truncated to an Integral. Delegates to x. trunc ().

#### Compressions \_\_\_

Python contains several modules for working with compressed files. The builtin function zip does *not* have anything to do with zipping, think instead of a zipper.

There are three different concepts with compressions:

- compression of data
- compression of a single file (e.g. gzip, bz2)
- compression of archives, ie. zip-files with multple files

## Compression of data

Module Description

zlib Compression and decompression of data (strings), using the zlib library.

bz2 Sequential compression and decompression using classes BZ2Compressor and BZ2Decompressor, or One-shot (de)compression though functions compress() and decompress().

#### Compression of single file

Module Description

gzip Read and write gzip-compressed files as were they normal files, using the GzipFile class. bz2 Read and write bz2-compressed files as were they normal files, using the BZ2File class.

## Compression of archives

Module Description

zipfile Work with ZIP archives.

See the method <code>ZipFile.open</code> for reading a single file in the archive as a normal file.

tarfile Read and write tar archive files.

shutil The function make archive provides means for packaging a directory into a archive.

## List of modules and packages in base distribution\_

Built-ins and content of python **Lib** directory. The subdirectory Lib/site-packages contains platform-specific packages and modules.

[Main distributions (Windows, Unix), some OS specific modules may be missing]

#### Standard library modules

aifc

Operation Result

\_\_builtin\_\_ Provide direct access to all `built-in' identifiers of Python, e.g. \_\_builtin\_\_ .open is the full name

for the built-in function open ().

\_\_future\_\_ Future statement definitions. Used to progressively introduce new features in the language.

main Represent the (otherwise anony mous) scope in which the interpreter's main program execute

Represent the (otherwise anony mous) scope in which the interpreter's main program executes --commands read either from standard input, from a script file, or from an interactive prompt.

Typical idiom to check if a code was run as a *script* (as opposed to being *imported*):

if \_\_name\_\_ == '\_\_main\_\_':
 main() # (this code was run as script)

abc (new in 2.6) Abstract Base Classes (ABC) [PEP 3119]. Equivalent of Java interfaces. The module

collections defines interfaces/ABCs for many behaviors/protocols/data structures (Iterable,

Hashable, Sequence, Set, etc...).
Stuff to parse AIFF-C and AIFF files.

any dbm Generic interface to all dbm clones. (dbhash, gdbm, dbm, dumbdbm).

argparse Parser for command-line options, arguments and sub-commands. For more C-like command-line

processing, see getopt.

array Efficient arrays of numeric values.

ast (new in 2.6) Helpers to process Trees of the Python Abstract Syntax grammar.

asynchat A class supporting chat-style (command/response) protocols.

asy ncore Basic infrastructure for asy nchronous socket service clients and servers.

atexit Register functions to be called at exit of Python interpreter.

audiodev Classes for manipulating audio devices (currently only for Sun and SGI). Deprecated since 2.6.

audioop Manipulate raw audio data. 2.5: Supports the a-LAW encoding. base64 Conversions to/from base64 transport encoding as per RFC-1521.

BaseHTTPServer HTTP server base class

Bastion "Bastionification" utility (control access to instance vars).

bdb A generic Python debugger base class. binascii Convert between binary and ASCII.

binhex Macintosh binhex compression/decompression.

bisect Bisection algorithms.

bsddb (Optional) improved BSD database interface [package].

bz2 BZ2 compression.

calendar Calendar printing functions.

cgi Wraps the WWW Forms Common Gateway Interface (CGI).

CGIHTTPServer CGI-savvy HTTP Server.

cgitb Traceback manager for CGI scripts.

chunk Read IFF chunked data.

cmath Mathematical functions for complex numbers. See also math. cmd A generic class to build line-oriented command interpreters.

emp Efficiently compare files, boolean outcome only.

cmpcache Same, but caches 'stat' results for speed.

code Utilities needed to emulate Python's interactive interpreter.

codecs Lookup existing Unicode encodings and register new ones. 2.5: support for incremental codecs.

codeop Utilities to compile possibly incomplete Python source code.

collections High-performance container datatypes. 2.4: The only datatype defined is a double-ended queue

deque, 2.5: Type deque has now a remove method. New type defaultdict. 2.6: New type namedtuple. **Define many ABCs (Abstract Base Classes)** like Container, Hashable, Iterable,

Sequence, Set...

colorsvs Conversion functions between RGB and other color systems.

commands Execute shell commands via os.popen [Unix]. compileall Force "compilation" of all .py files in a directory. ConfigParser Configuration file parser (much like windows .ini files).

contextlib Utilities for with statement contexts. Cookie HTTP state (cookies) management.

copy Generic shallow and deep copying operations.

Helper to provide extensibility for modules pickle/cPickle. copy\_reg

Faster, Cimplementation of pickle. cPickle cProfile Faster, Cimplementation of profile. crypt Function to check Unix passwords [Unix]. Faster, Cimplementation of StringIO. cStringIO

Tools to read comma-separated files (of variations thereof), 2.5; Several enhancements. csv

"Foreign function" library for Python. Provides C compatible data types, and allows to call functions ctypes

in dlls/shared libraries. Can be used to wrap these libraries in pure Python.

Terminal handling for character-cell displays [Unix/OS2/DOS only]. curses

Improved date/time types (date, time, datetime, timedelta). 2.5: New method datetime

strptime(string, format) for class datetime. 2.6: strftime() new format code %f expanding to

number of s.

dbhash (g)dbm-compatible interface to bsdhash.hashopen.

decimal Decimal floating point arithmetic.

difflib Tool for comparing sequences, and computing the changes required to convert one into another.

2.5: Improved SequenceMatcher.get\_matching\_blocks() method.

dircache Sorted list of files in a dir, using a cache. Deprecated since 2.6.

Defines a class to build directory diff tools on. diremp

By tecode disassembler. dis

distutils Package installation system. 2.5: Function setup enhanced with new keyword parameters

requires, provides, obsoletes, and download url [PEP314].

Registers a module in the Python package index (PyPI). This command plugin adds the register distutils.command.register

command to distutil scripts.

distutils.debug

distutils.emxccompiler

distutils.log

distutils.sy sconfig In 2.7 moved to separate module sysconfig.

Call C functions in shared objects [Unix]. Deprecated since 2.6. dl

doctest Unit testing framework based on running examples embedded in docstrings. 2.5: New SKIP option.

New encoding arg to testfile () function.

Creation of self-documenting XML-RPC servers, using py doc to create HTML API doc on the fly. 2.5: DocXMLRPCServer

New attribute rpc paths.

dospath Common operations on DOS pathnames. dum bdbm A dumb and slow but simple dbm clone.

Print python code that reconstructs a variable. dump

dummy thread

dummy\_threading

Helpers to make it easier to write code that uses threads where supported, but still runs on Python

versions without thread support. The dummy modules simply run the threads sequentially.

A package for parsing, handling, and generating email messages. New version 3.0 dropped various email

deprecated APIs and removes support for Python versions earlier than 2.3. 2.5; Updated to version

New codecs: idna (IDNA strings), koi8 u (Ukranian), palmos (PalmOS 3.5), punycode encodings

(Puny code IDNA codec), string escape (Python string escape codec: replaces non-printable chars w/Python-style string escapes). New codecs in 2.4: HP Roman8, ISO 8859-11, ISO 8859-16,

PCTP-154, TIS-620; Chinese, Japanese and Korean codecs.

Standard errno system symbols. The value of each symbol is the corresponding integer value. errno

Class based built-in exception hierarchy. exceptions fcntl The fcntl() and ioctl() system calls [Unix].

filecmp File and directory comparison.

fileinput Helper class to quickly write a loop over all standard input files. 2.5: Made more flexible (Unicode

filenames, *mode* parameter, etc...)

find Find files directory hierarchy matching a pattern.

fnmatch Filename matching with shell patterns.

formatter Generic output formatting.

Floating point exception control [Unix]. fpectl

fpformat General floating point formatting functions. Deprecated since 2.6.

fractions (new in 2.6) Rational Numbers. An FTP client class. Based on RFC 959. ftplib

Tools for functional-style programming. See in particular function partial() [PEP309]. functools

future builtins (new in 2.6) Python 3 builtins. Provides functions that exist in 2.x, but have different behavior in

Python 3 (ascii, map, filter, hex...). To write Python 3 compatible code, import the functions from

this module, e.g.:

from future\_builtins import map

n 1

...code using Python3-syle map()...

gc Perform garbage collection, obtain GC debug stats, and tune GC parameters. 2.5: New get count()

function. gc.collect() takes a new generation argument.

gdbm GNU's reinterpretation of dbm [Unix].

getopt Standard command line processing in C getopt () style. See also argparse.

getpass Utilities to get a password and/or the current user name.

gettext Internationalization and localization support.

glob Filename "globbing" utility.
gopherlib Gopher protocol client interface.
grp The group database [Unix].

grep 'grep' utilities.

gzip Read & write gzipped files.

hashlib Secure hashes and message digests.

heapq Heap queue (priority queue) helpers. 2.5: nsmallest() and nlargest() takes a key key word

param

hmac HMAC (Key ed-Hashing for Message Authentication).

hotshot.stones Helper to run the pystone benchmark under the Hotshot profiler.

htmlentity defs HTML character entity references.

httmllib HTML2 parsing utilities. Deprecated since 2.6; see HTMLParser-class.

HTMLParser Simple HTML and XHTML parser.

httplib HTTP1 client class.

idlelib (package) Support library for the IDLE development environment.

ihooks Hooks into the "import" mechanism. Deprecated since 2.6.

imageop Manipulate raw image data. Deprecated since 2.6; removed in Python 3.

imaplib IMAP4 client. Based on RFC 2060.

imghdr Recognizing image files based on their first few by tes.

imp Access the import internals.

imputil Provides a way of writing customized import hooks.

inspect Get information about live Python objects.

io (new in 2.6) Core tools for working with streams [PEP 3116]. Define Abstract Base Classes

RawIOBase (I/O operations: read, write, seek...), BufferedIOBase (buffering), and TextIOBase

(reading & writing strings).

itertools Tools to work with iterators and lazy sequences. 2.5: islice() accepts None for start & step args.

2.6: Several new functions: izip longest, product, combinations, permutations.

json (new in 2.6) JSON (JavaScript Object Notation) interchange format support.

keyword List of Python keywords.

knee A Python re-implementation of hierarchical module import.

linecache Cache lines from files.

hinux dev / audio support. Replaced by ossaudiodev (Linux).

locale Support for number formatting using the current locale settings. 2.5: format() modified; new

functions format string() and currency()

logging (package) Tools for structured logging in log4j style.

macpath Pathname (or related) operations for the Macintosh [Mac].

macurl2 path Mac specific module for conversion between pathnames and URLs [Mac].

mailbox Classes to handle Unix style, MMDF style, and MH style mailboxes. 2.5; added capability to modify

mailboxes in addition to reading them.

mailcap Mailcap file handling (RFC 1524). marshal Internal Python object serialization.

markupbase Shared support for scanning document type declarations in HTML and XHTML.

math Mathematical functions. See also cmath

md5 MD5 message digest algorithm. 2.5: Now a mere wrapper around new library hashlib.

Deprecated since 2.6, use hashlib module instead.

mhlib MH (mailbox) interface. Deprecated since 2.6.

mimetools Various tools used by MIME-reading or MIME-writing programs. Deprecated since 2.6.

mimety pes Guess the MIME type of a file.

m odu lefin der

mutex

MimeWriter Generic MIME writer. Deprecated since 2.3, use email package instead.

mimify Mimification and unmimification of mail messages. Deprecated since 2.6, use email package

instead.

mmap Interface to memory-mapped files - they behave like mutable strings.

Tools to find what modules a given Python program uses, without actually running the program.

msilib Read and write Microsoft Installer files [Windows].
msv crt File & Console Windows-specific operations [Windows].

multifile A readline()-style interface to the parts of a multipart message. Deprecated since 2.6.

multiprocessing (new in 2.6) Process-based "threading" interface. Allows to fully leverage multiple processors on

a machine [Windows, Unix] [PEP 371].

Mutual exclusion -- for use with module sched. See also std module threading, and glock.

netrc Parses and encapsulates the netrc file format.

new Creation of runtime internal objects (interface to interpreter object creation functions). Deprecated

since 2.6.

nis Interface to Sun's NIS (Yellow Pages) [Unix]. 2.5: New domain arg to his match () and

interface to bail of the (Tenon Tages) [Onia]. 2.3. Hen domain and to his imacenty and

nis.maps().

nntplib An NNTP client class. Based on RFC 977.

Common operations on Windows pathnames [Windows]. ntpath nturl2path Convert a NT pathname to a file URL and vice versa [Windows].

Numeric Abstract Base Classes (ABC) [PEP 3141]. Define a type hierarchy for numbers: numbers

Number, Complex, Real, Rational, Integral.

olddifflib Old version of difflib (helpers for computing deltas between objects)?

Standard operators as functions. 2.5: itemgetter() and attrgetter() now supports multiple operator

fields.

Improved command-line option parsing library (see also getopt). 2.5: Updated to Optik library 1.51. optparse

OS routines for Mac, DOS, NT, or Posix depending on what system we're on. 2.5: os.stat() return

time values as floats; new constants to os.lseek(); new functions wait3() and wait4(); on

FreeBSD, os.stat() returns times with nanosecond resolution.

os.path Common pathname manipulations. os2emxpath os.path support for OS/2 EMX. packmail Create a self-unpacking shell archive.

Access Python parse trees. parser pdb A Python debugger.

Pickling (save/serialize and restore/deserialize) of Python objects (a faster C implementation exists pickle

in built-in module: cPickle). 2.5: Value returned by \_\_reduce\_\_() must be different from None.

Tools to analyze and disassemble pickles. pickletools Conversion pipeline templates [Unix]. pipes

Tools to extend the module search path for a given package. 2.5; PEP302's import hooks support; pkgutil

works for packages in ZIP format archives.

platform Get info about the underlying platform.

poly Poly nomials.

os

rand

Spawn a command with pipes to its stdin, stdout, and optionally stderr. Superseded by module рорен2

subprocess since 2.4. Deprecated since 2.6.

A POP3 client class. poplib

Most common POSIX system calls [Unix]. posix Common operations on POSIX pathnames. posixpath

Support to pretty-print lists, tuples, & dictionaries recursively. pprint

Support for regular expressions (RE) - see re. pre

Class for profiling python code. 2.5: See also new fast Cimplementation oprofile profile

pstats Class for printing reports on profiled python code. 2.5: new stream arg to Stats constructor.

Pseudo terminal utilities [Linux, IRIX]. pty

pwd The password database [Unix].

py\_compile Routine to "compile" a .py file to a .py c file.

Parse a Python file and retrieve classes and methods. py clbr

py doc Generate Python documentation in HTML or text for interactive use. Interface to the Expat XML parser. 2.5: now uses V2.0 of the expat parser. pyexpat

Py Unit Unit test framework inspired by JUnit. See unittest.

Queue A multi-producer, multi-consumer queue. 2.6: New queue variants PriorityQueue and

LifoQueue.

quopri Conversions to/from quoted-printable transport encoding as per RFC 1521.

Don't use unless you want compatibility with C's rand().

random Random variable generators.

Regular Expressions. re

GNU readline interface [Unix]. readline

Convert old ("regex") regular expressions to new syntax ("re"). reconvert Backward compatibility for module "regexp" using "regex". regexp

Flags for regex.set\_syntax(). regex\_syntax

Regexp-based split and replace using the obsolete regex module. regsub

Alternate repr () implementation. repr Resource usage information [Unix]. resource

rexec Restricted execution facilities ("safe" exec, eval, etc).

rfc822 Parse RFC-8222 mail headers. Read and write 'SGI RGB' files. rgbing

rlcompleter Word completion for GNU readline 2.0 [Unix]. 2.5: Doesn't depend on readline anymore; now

works on non-Unix platforms.

Parse robot.txt files, useful for web spiders. robotparser sched A generally useful event scheduler class.

select Waiting for I/O completion.

A Set datatype implementation based on dictionaries. Deprecated since 2.6, use built-in types set sets

and frozenset instead.

sgmllib A parser for SGML, using the derived class as a static DTD.

SHA-1 message digest algorithm. 2.5: Now a mere wrapper around new library hashlib. sha

Deprecated since 2.6, use hashlib instead.

shelve Manage shelves of pickled objects.

1 1

shlex Lexical analyzer class for simple shell-like syntaxes. shutil Utility functions for copying files and directory trees.

signal Set handlers for asynchronous events.

SimpleHTTPServer Simple HTTP Server.

SimpleXMLRPCServer Simple XML-RPC Server. 2.5: New attribute rpc\_paths.

site Append module search paths for third-party packages to sys.path.

smtpd An RFC 2821 SMTP server. smtplib SMTP/ESMTP client class.

sndhdr Several routines that help recognizing sound.

socket Socket operations and some related functions. Now supports timeouts thru function

settimeout(t). Also supports SSL on Windows. 2.5: Now supports AF\_NETLINK sockets on Linux; new socket methods recv\_buf(buffer), recvfrom\_buf(buffer), getfamily(), gettype() and

getproto().

SocketServer Generic socket server classes.

spwd Access to the UNIX shadow password database [Unix].

sqlite3 DB-API 2.0 interface for SQLite databases.
sre Support for regular expressions (RE). See re.
stat Constants/functions for interpreting results of os.

statvs constants for interpreting statvs struct as returned by os.statvs() and os.fstatvs() (if they

exist). Deprecated since 2.6.

string A collection of string operations (see Strings).

StringIO File-like objects that read/write a string buffer (a faster C implementation exists in built-in module

cStringIO).

stringprep Normalization and manipulation of Unicode strings.

struct Perform conversions between Python values and C structs represented as Python strings. 2.5; faster

(new pack() and unpack() methods); pack and unpack to and from buffer objects via methods

pack into and unpack from.

subprocess management. Replacement for os.system, os.spawn\*, os.popen\*, popen2.\* [PEP324]

sunau Stuff to parse Sun and NeXT audio files.

sunaudio Interpret sun audio headers.

symbol Non-terminal symbols of Python grammar (from "graminit.h").

symtable Interface to the compiler's internal symbol tables. sys System-specific parameters and functions.

sy sconfig Provides access to Python's configuration information like the list of installation paths and the

configuration variables relevant for the current platform.

sy slog Unix sy slog library routines [Unix].

tabnanny Check Python source for ambiguous indentation.

tarfile Tools to read and create TAR archives. 2.5: New method TarFile.extractall().

telnetlib TELNET client class. Based on RFC 854.

tempfile Temporary files and filenames. 2.6: New classes SpooledTemporaryFile and

NamedTemporaryFile.

termios POSIX style tty control [Unix].
test Regression tests package for Python.
textwrap Tools to wrap paragraphs of text.

thread Multiple threads of control (see also threading below).

threading New threading module, emulating a subset of Java's threading model. 2.5: New function

stack size([size]) allows to get/set the stack size for threads created. 2.6: Several functions

renamed or replaced by properties, new property Thread.ident. See also new module

multiprocessing.

threading\_api (doc of the threading module).
time Time access and conversions.

timeit Benchmark tool.

Tix Extension widgets for Tk.
Tkinter Python interface to Tcl/Tk.

toaiff Convert "arbitrary" sound files to AIFF (Apple and SGI's audio format). Deprecated since 2.6.

token Token constants (from "token.h").
tokenize Tokenizer for Python source.

trace Tools to trace execution of a function or program.

traceback Extract, format and print information about Python stack traces.

tty Terminal utilities [Unix]. turtle LogoMation-like turtle graphics.

types Define names for all type symbols in the std interpreter.

tzparse Parse a timezone specification.

unicodedata Interface to unicode properties. 2.5: Updated to Unicode DB 4.1.0; Version 3.2.0 still available as

unicodedata.ucd\_3\_2\_0.2.6: Updated to Unicode DB 5.1.0.

unittest Python unit testing framework, based on Erich Gamma's and Kent Beck's JUnit.

urllib Open an arbitrary URL.

urllib2 An extensible library for opening URLs using a variety of protocols.

urlparse Parse (absolute and relative) URLs.

user Hook to allow user-specified customization code to run.

aber 1100x to allow aber specified castonization code to rail.

UserDict A wrapper to allow subclassing of built-in dict class (useless with new-style classes. Since Python

2.2, dict is subclassable).

UserList A wrapper to allow subclassing of built-in list class (useless with new-style classes. Since Python 2.2,

list is subclassable)

UserString A wrapper to allow subclassing of built-in string class (useless with new-style classes. Since Python

2.2, str is subclassable).

util some useful functions that don't fit elsewhere !!

uu Implementation of the UUencode and UUdecode functions.

uuid UUID objects according to RFC 4122.

warnings Python part of the warnings subsystem. Issue warnings, and filter unwanted warnings.

wave Stuff to parse WAVE files.

weakref Weak reference support for Python. Also allows the creation of proxy objects. 2.5: new methods

iterkeyrefs(), keyrefs(), itervaluerefs() and valuerefs().

webbrowser Platform independent URL launcher. 2.5: several enhancements (more browsers supported, etc...).

whatsound
Several routines that help recognizing sound files.
whichdb Guess which db package to use to open a db file.

whrandom Wichmann-Hill random number generator (obsolete, use random instead).

winsound Sound-playing interface for Windows [Windows]. wsgiref WSGI Utilities and Reference Implementation.

xdrlib Implements (a subset of) Sun XDR (eXternal Data Representation).

xml.dom Classes for processing XML using the DOM (Document Object Model). 2.3: New modules

expatbuilder, minicompat, NodeFilter, xmlbuilder.

xml.etree.ElementTree Subset of Fredrik Lundh's ElementTree library for processing XML.

xml.parsers.expat An interface to the Expat non-validating XML parser. xml.sax Classes for processing XML using the SAX API.

xmlrpclib An XML-RPC client interface for Python. 2.5: Supports returning datetime objects for the XML-RPC

date type.

xreadlines Provides a sequence-like object for reading a file line-by-line without reading the entire file into

memory. Deprecated since release 2.3. Use for line in file instead. Removed since 2.4

zipfile Read & write PK zipped files. 2.5: Supports ZIP64 version, a .zip archive can now be larger than

4GB. 2.6: Class ZipFile has new methods extract() and extractall().

zipimport ZIP archive importer.

zlib Compression compatible with gzip. 2.5: Compress and Decompress objects now support a copy ()

method.

zmod Demonstration of abstruse mathematical concepts.

## Workspace exploration and idiom hints \_\_\_

```
dir(object)
                                          list valid attributes of object (which can be a module, type or class object)
dir()
                                          list names in current local symbol table.
if __name__ == '__main__':
                                          invoke main() if running as script
    main()
map(None, 1st1, 1st2, ...)
                                          merge lists; see also zip(lst1, lst2, ...)
                                          create a copy b of sequence a
b = a[:]
b = list(a)
                                          If a is a list, create a copy of it.
a,b,c = 1,2,3
                                          Multiple assignment, same as a=1; b=2; c=3
for key, value in dic.items(): ...
                                          Works also in this context
if 1 < x <= 5: ...
                                          Works as expected
for line in fileinput.input(): ...
                                          Process each file in command line args, one line at a time
                                          (underscore) in interactive mode, refers to the last value printed.
```

## Python Mode for Emacs\_\_\_\_

Emacs goodies available here.

(The following has not been revised, probably not up to date - any contribution welcome -)

```
Type C-c ? when in python-mode for extensive help.

INDENTATION

Primarily for entering new code:

TAB indent line appropriately

LFD insert newline, then indent

DEL reduce indentation, or delete single character

Primarily for reindenting existing code:

C-c: guess py-indent-offset from file content; change locally

C-u C-c: ditto, but change globally

C-c TAB reindent region to match its context

C-c < shift region left by py-indent-offset

C-c > shift region right by pv-indent-offset
```

```
MARKING & MANIPULATING REGIONS OF CODE
C-c C-b
          mark block of lines
M-C-h
             mark smallest enclosing def
C-u M-C-h
             mark smallest enclosing class
C-c #
             comment out region of code
C-u C-c #
              uncomment region of code
MOVING POINT
с С-р
           move to statement preceding point
C-c C-n
            move to statement following point
             move up to start of current block
C-c C-u
             move to start of def
move to start of class
M-C-a
C-u M-C-a
             move to end of def
M-C-e
C-u M-C-e
             move to end of class
EXECUTING PYTHON CODE
C-c C-c sends the entire buffer to the Python interpreter
      sends the current region
      starts a Python interpreter window; this will be used by
C-c !
       subsequent C-c C-c or C-c | commands
VARIABLES
py-indent-offset
                    indentation increment
py-block-comment-prefix comment string used by py-comment-region
py-python-command shell command to invoke Python interpreter
                            t means always scroll Python process buffer
py-scroll-process-buffer
py-temp-directory directory used for temp files (if needed)
py-beep-if-tab-change ring the bell if tab-width is changed
```

## Changes to this document

April, 2013 (Stefan McKinnon Høj-Edwards)

Corrections

- Added strikethrough to deprecated modules in module-list.
- Corrected links in modules list.
- Added a recipee for the secret re.Scanner.
- · Added context manager methods to special methods in classes.

Oct, 2011 (Stefan McKinnon Høj-Edwards)

Upgraded to Python 2.7

Prior to Oct. 2011,

see Last updated on-list
